I only do this stuff for a hobby, but my own bugaboo are the wierd things
associated with analytical equations and the wierd constraints that make
wideband matching work. The wideband matching thing is amazing, and
the various concepts that intimately connect the real and imaginary
parts of a real world impedance are also amazing. I have been an EE
and CompSci person for many years (25+), and when reinvigorating
my EE hobby (playing with low-UHF/UHF stuff), and learning about the
wideband matching stuff, it has been very surprising. I must have forgotten
alot since school!!!

The good thing is that this stuff is one of my many hobbies, where I
become MUCH TOO deeply involved, but when these kinds of hobbies
turn into a real world job, then the fun goes away. So, I do understand

the frustration of doing work that one theoretically enjoys, but doing
it for a living quickly becomes painful and unpleasant. I let my FreeBSD
hobby turn into a job, which made me some money, but caused me
to loose the enjoyment of my hobby :-(.

In a way, I'd enjoy the kind of work that you apparently do, but having
to actually produce the resulting work, with almost impossible
constraints, would quickly ruin the fun. Of course, in my case, it makes
the big assumption that I'd have the skills to do the work in the real world, and
there is a big difference between a motivated hobby and a difficult
and overly challenging job.

Anyway, sounds like you really need to enjoy your weekend!!! :-).

While a TRF is still nice for receiving broadcasts in the LF broadcast band and may have been useful for receiving broadcasts in the sparsely populated MF band in the old days, a loaded Q from 40 to 100 means a (-3 dB bandwidth) of 15 .. 40 kHz at the upper end of the MF broadcast band. This makes such receivers practically useless today, with a lot of high power transmitters at every 9 kHz.

Regarding old VHF/UHF receiver circuits, most of them are more or less useless today, since most of them were designed to minimise the noise figure (which was still very bad according to current standards) at all costs and thus, the strong signal handling completely useless for the situation today, with a lot of services in VHF/UHF.

I was a bit worried when a facsimile of a radio book originally published around 1950 was republished last year. In those old days there was very little activity above 30 MHz (the FM broadcasts started around 1952 and TV in 1955 over here) so the harmonic suppression of these HF transmitters were completely inadequate according to current standards. If someone would build a transmitter according to these designs today, it would create a large number of interference complaints.

When building something from an old design, you really have to consider, is the environment the same as when the circuit was initially designed.

Radio Shack in Canada is definitely phasing out all the small electronic discrete components. Bit by bit this stuff goes on sale and when it is gone, it does not get replaced. I bought three packs of 1N34's from RS about 6 months ago - 99 cents for a package of 10 (or maybe it was 20). The guy said they won't be getting anymore in. Same thing with packs of resistors, capacitors, etc.

The NorCal BLT Tuner works fine. I built it and made a small change to extend its tuning range, in that way it would tune my 75 m horizontal loop on all bands from 80m-10m including WARC.

See my homebrew page on http://www.qsl.net/la3za/Homebrew.html and follow link about antenna tuner from there.

I started at age 13 with an interest in ham radio. At that time, the frequency to be on was 3.5 Mc (that's right, megacycles). After many years of going to schools and being a technician and then an engineer, I'm now doing work at S Band (2400 MHz) and using devices with S11's and S22's (input and output reflection coefficients) which are shorts,basically. The design constraints are no money, no room and no power supply voltage with no current drain. I like challenge, but my name is Steve Carlton and not Don Quixote. I'm really good with rf having a lot of patience and magic fingers for spurs, desense, etc., but I wish I could get the hay out of Dodge. Anyone got a cure for the rf blues? Before anyone tells me to get into antenna design, I have to do that also with only a HP8410 and a few N adapters. BTW, anyone have a cheap rf anechoic chamber out there that's compatible with 2.4GHz? How about a cheap two or three stub tuner for 12 cm?

I'm probably throwing another wrench into the mechanism here, but I still
miss Allied Electronics before they had Radio Shack. Their catalogs were
gold when I was a kid. They had 1N34's and crystal radio sets in them
using the old xtal and cat whisker detector along with a single ear "can"
headphone. My first radio was the Space Spanner under the Knight Kit
banner. It was a real dog, but I thought it was a Cadillac at the time.
With all the fancy stuff now available, I still feel myself priviledged
over the kids now to have had that opportunity then. It surely brought me
joy even with no money in my pocket to buy an S line or other impossible
dream.

My great memory: 100 N. Western Avenue; Chicago, Ill.

I need to Baker Act myself. :-)

One question: When the final values are set, does the tuner circuit
arrive at an equivalent L network or is it still a pi or T with
significant values of C in the input and output shunts for the pi and a
low value of C for each series C for the T? This addresses the efficiency
of match. An L match will give you minimum circulating currents. Do some
simulations if curious about this.

One of the very earliest UHF semiconductor devices I remember seeing was
a germanium UHF diode (1N23?) used in television UHF tuners as a mixer.

>Younger people often want to replace old with something new just because
>it's old, I always wonder, what are they really trying to do...?

It's not just younger people, either. Some people, of all ages, push "new" as
equivalent to "better". Often they do this without proof, or without
considering all of the measures of what makes something "better".

One motivation for pushing new things is to sell the new things, whether people
need new ones or not.

>If the new only works as well as the old, then the old is "proven
>technology" not "obsolete junk"?

Exactly. Sometimes newer really is better, sometimes it's worse. Often there
are unforeseen consequences to new things - and sometimes unforeseen benefits.

3337. any Wavetek 3001 gurus??

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-10-26 19:33:36 UTC
From: lagagnon@fakesprint.ca
Message-ID: <3dbaede6.2676132@news.sprint.ca>
Source record: 40400

I have a Wavetek 3001 signal generator with the following symptoms:

- every 40 MHz, for about 8-9 MHz the M34 PLL module unlocks (1-8MHz, 40-49, 80-89,....etc). All other frequency outputs are very good and lock solidly with a good waveform.

- this PLL unlock condition is not associated with the Accuracy unlock light blinking on the front panel, however it can be seen that M34 is unlocked by putting a scope on the Video test point. This 10 MHz waveform is distorted and appears to have a lot of harmonics.

- the M34 leveler voltage does not increase as would be expected, but the Phase Detector Output voltage to the M9W wide oscillator is much higher than normal (>5v, should normally be around 1v).

I have removed M34 and done the basic voltage checks as per the troubleshooting guide and all seems OK. I suspect that perhaps because the leveler circuit and unlock circuit are not sensing a true unlock that the switchable 10/20MHz filter is not being switched in to lock on the correct mixed frequency.

I hope someone out there with a lot of Wavetek 3001 experience might have experienced the same or have some ideas??? Any assistance greatly appreciated.

**NOW AVAILABLE **
Program BOTLOAD2.exe"

An improved version of "Botload" which is now no longer available. This simple program calculates base feedpoint impedance, R+jX, of any vertical antenna height and diameter. Also value of inductive or capacitive bottom loading component. Also, for given length and diameter of loading coil, the number of turns, winding pitch and wire-gauge.

Vary antenna height from keyboard to find heights at which feedpoint resistance matches 50 or 75-ohm coaxial feedlines. Or any other particular Zo. Metric and Imperial dimensions displayed.

Download BOTLOAD in a few seconds. Run immediately.

I don't know...maybe a cyanide capsule? If that is not appealing, then I would always vote for EXTENDED ISLAND VACATION. A real island too, not one of those Caribbean Islands but something out in the middle of the Pacific Ocean. One with no lights, no phones, no motor cars... Would be very relaxing not to have to deal with anything for a month or so.

The store nearest to me here in Montreal was selling off the parts two
years ago, in the summer. (Actually, I'd picked up some nice boxes,
raw speakers, and other parts maybe six months before that, but at the
time it just seemed like the usual clearing out of old stock. The
kind that always made the parts more reasonable than the regular
Radio Shack price.) It was a "buy 1, get 2 free" offer (if they
weren't the same item, you'd pay for the highest priced one) and
I seemed to stumble on it mid-sale, meaning I missed some of
the items I had been tempted by at full price. I didn't see
a similar sale (or any announcement) at the other stores, but
at some point, there weren't parts at the other stores either.

I've always been a little puzzled by it, since there was no
big announcement of a clearance, and at the time it almost
seemed as if it was one or more stores making their own decision
to dump the parts.

Except for a couple of times when I've been stuck, I've never routinely
bought parts at Radio Shack. It's always been way too expensive, and
there are local stores here that I can get most of the same sort of parts.
The exceptions were a few items each year that Radio Shack had decided
to carry, and it was just easier to get them there. And when they
cleared out old items, and you could pick up those neat ICs and things
for a minimal price.

But nevertheless, it is a shame. Considering what it often costs
to buy mail order (not so much the individual price, but with shipping
and a minimum order, it often requires a chunk of money, and planning)
sometimes it was just worth paying a higher price on one component
for the sake of being able to buy it nearby.

I'm not sure what you're point is, Paul. OSCTRACK is for superhets,
specifically those tuned by ganged variable capacitors. Such superhet receivers
are still being designed today - almost exclusively by amateurs. (This is
rec.radio.amateur.homebrew, of course).

Perhaps your point is that old TRF AM BC receivers are no longer very useful
for reception today, compared to superhets, but that's another issue.
>
>Regarding old VHF/UHF receiver circuits, most of them are more or less

>figure (which was still very bad according to current standards) at
>all costs and thus, the strong signal handling completely useless for
>the situation today, with a lot of services in VHF/UHF.

All depends on the situation. In many parts of the USA, such equipment would
still be usable.

But even if that equipment is truly "useless" today, the reason is not because the equipment and its design concepts are old.

Is a simple "crystal" receiver useless today?
>
>I was a bit worried when a facsimile of a radio book originally

>standards. If someone would build a transmitter according to these
>designs today, it would create a large number of interference
>complaints.

Quite possible, but not guaranteed. Many old designs had surprisingly clean signals, because the amateur bands are not perfectly related harmonically. Amateur transmitters with high harmonic output would interfere with other services
using HF.
>
>When building something from an old design, you really have to
>consider, is the environment the same as when the circuit was
>initially designed.

I agree 100%. And that is true of designs that are much newer than 1950.

For example, many solid-state HF receiver designs suffer from relatively poor dynamic range performance compared to their vacuum-tube counterparts. This was particularly true of early solid-state designs, and designs where most of the emphasis was placed on certain factors (sensitivity, simplicity, compactness) while others were deemphasized.

As another example, many designs using synthesizers suffer from poor phase-noise performance compared to older designs using LC and crystal oscillators.

End result is that under modern-day HF amateur receiving conditions, some older designs will outperform newer designs of equivalent cost and complexity.

Here's an example:

http://www.arrl.org/tis/info/pdf/020910qex036.pdf

Note that some of the best performers do not use frequency synthesis or up-conversion. In fact, the modified R-4C that appears to be the overall champion
is a design more than 30 years old, using vacuum tubes (!) for most of the stages. The Elecraft K2 is a low-cost single conversion design, yet it compares well with designs costing several times as much.

3343. Re: Anyone Have a Cure for RF Burnout?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-10-26 22:21:20 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <urm5b04vlbj387@corp.supernews.com>
Source record: 40405

No money, no room, no power consumption. . . is that what's troublin' you, Bunky? (Where's the Old Philosopher when we need him?) You don't have RF burnout, you've got engineering burnout. Creating something that's *good enough*, given a set of mutually exclusive requirements, is the name of the game. The sign over my desk summarizes it: "Anyone can design a bridge that will stand up. It takes an engineer to design a bridge that will barely stand up."

What I'd do if I were you is to take a long look at the various industries that have need for RF engineers. They run the gamut from ones making radio controlled toys and garage door openers, to smart munitions, satellite and space communications, and test equipment. Design criteria vary a huge amount, and you might find a situation that suits you better. For example, I've worked at a small company that made essentially custom test units. The instrument sold was often hand built. For these, it was better for me to use a $20 part if it would save 15 minutes of design time over using a $5 part. I've also designed the RF section of a motion detector to be mass produced at very low cost. There, it was worthwhile to spend an extra week or two to knock a dollar off the cost. And I've done design for very high speed (up to 50 GHz bandwidth, around 10 ps risetime) oscilloscope sampling systems, where if we could figure out any way to do it all (selected or specially built components, highly skilled assemblers, custom production equipment, whatever), it was ok -- customers would pay if they could get it at all. Each was a challenge -- it's always a challenge, otherwise someone else will do it cheaper or quicker or better and get the business -- but the challenges were very different. Look around, and you might find a set of challenges that suits you better than the ones you're currently being dealt.

RF skills also position you well for EMC work, if that's your bag. I've found, though, that it's often hard to win at that game, since so many companies leave EMC considerations to the very last, when it's impossible to fix the problems except with klugy and expensive methods. There are a few enlightened companies that have the sense to incorporate good EMC practice from the very beginning of a design, and one of those might not be too bad to work for in the EMC field. I've done some consulting in EMC, so was able to turn down the jobs that didn't have much chance of meeting the companies' unrealistic expectations.

Consulting is a good way to go. Once you've built up enough business to keep your stomach full, you can turn down jobs that don't suit you for one reason or another. And there are a lot of companies whose main product isn't RF based so who don't have good in-house RF talent. But watch out! Once you've escaped the cube farm, you'll never want to go back!

Thanks for the encouragement, Roy. There is a need for rf guys like me,
but not apparently in my age group. The US is changing now and is looking
to putting all its work outside in the "Global" environment, whatever that
is. I guess it means that some young guy in Sri Lanka will design a
circuit and ship it to wherever, where it'll be developed into something
shipable and then that's that. Why would someone need experience? You
find someone young and hungry, give him temporary work, get the job done,
and then go on to find the next one. No benefits, low overhead, no

problem. There is a minor glitch to all of this: How do you get advanced systems and new technology? Answer: don't worry, we'll (CEO's) be retired and won't have to worry. Don't believe me? Look around! It is happening right now.

Hi MIke,

It was probably a 1N21 which was used in all radars since the Flintstones.

Motto of a radar technician: First check the crystal current.

I had some 'similar' problems with my wavetek 3000 and it turned out to be the electrolytic capacitors.

As far as I could tell, they had dried out and started to leak current, enough to disturb the circuit module that was failing.

I don't know but you might have a similar problem, the 3001 is also a fairly old model and the capacitors might need replacing in the module that is showing the fault.

Steve WB4CZR

Maybe the problem is one of selling yourself, or maybe geographical area. I've turned down quite a few consulting jobs for RF design -- simply because I prefer to spend my time (at a lot lower pay) running my software business. I see a lot of demand for good RF design. Some of these outfits have already tried the cheap approach and, in fact, I think all the companies I've done RF work for have had RF engineers on staff. They just didn't have ones with enough skill or experience to handle the problem at hand. Admittedly, the market might be mostly for consultantants rather than cube dwellers. But I know at least a couple of people who have made a good living doing full time RF consulting work.

One of several advantages of consulting for companies who do have RF engineers is that they don't waste their money having you do the simple (and boring) stuff. It doesn't bother them a bit to have a high paid engineer spend his time standing in line at the single copy machine, struggle with obsolete computing tools, or spend hours in useless meetings. The engineer's efficiency and productivity don't have a dedicated cell in the CEO's spreadsheet, so it's not something they consider important or know how to deal with. On the other hand, the hours that a consultant spends, the work that's accomplished, and the amount that's paid are all very visible, so clients tend to want to get their money's worth. And most are astounded how much they get for their money -- it never occurs to them that it might not be how good you are, but the fact that your time isn't being squandered on non-productive tasks.

Good luck!

You can buy small quantities of Analog Devices parts over their website
at www.analog.com. They have good appnotes available for download
on all their products there.

There are several different logarithmic devices available, all with
wide dynamic range and good log accuracy.

>Steve WB4CZR
>I wish I could retire, burned-out and still working, rf engineer

Been there, done that, have my TS card punch re-oiled and
working. Stand in line. :-)

>BTW, anyone know of an easy way to match a GaAs fet on S11 or S22 without
>a stub tuner? S11&S22=0.9929 @ 179 deg, give me a break!

OK, OK, "stub tuners" means you are probably working at the
low end of S-band. That's just out of "never-never land" of L-band
or the transition from lumpy to distributed components. Difficult
area to play in. Here's a suggestion on problem solution that has

worked for others:

1. Stop the project for a while...take a break doing something
entirely different. If at work, make creative excuses on
doing something "important," using "approved PC speak"
to managers, etc. Acting lessons at a local little theater
group may help in that effort...even in interpersonal relations
with spouse, family, pets, etc.

2. Return to the project by VERY carefully examining your test
setup, check the test equipment as thoroughly as possible.
We are all human beans and may have overlooked something
while concentrating hard on a specific problem detail.

3. Concentrate on the paper equivalent of the circuit/system and
consider possible alternatives. A translator experienced in
PGMTT-speak might be handy...even one surnamed "Smith."

4. Get device back on bench in setup and power up. May the
Great Bird of the Galaxy not do anything on your fine outFET.

5. Maalox doesn't cure GaAs but Xanax might help. Reading
"Dilbert" strips at breakfast improves personal S12.

...click, click, click...sound of a TS card punch in operation... :-)

Gee, Steve, my feeling is that, as with most blues, it's mostly in the head. I've noticed in some of your past postings that you say that working with RF is a pain, or something of the sort. Personally, I enjoy it; I think I wouldn't be in it as a hobby if I didn't. And it happens to be nice to get paid to do work I like to do, too. Is it a challenge? Sure! Do we find all the answers we'd like? Of course not. But we manage to make the successes outnumber the failures, and in fact it's kinda fun fixing the problems overlooked the first time through. It may take some time to figure out what's going on sometimes, but in the end it never seems to be black magic, and we always manage to get the required processes under control.

Perhaps, as with other causes of the blues, a cure might be to get away from it for a while. Of course, if you gotta make a living at it, right now might not be such a wonderful time to make a change. On the other hand, right now might well be a great time to look for a chamber. We're about to make a move to smaller quarters, and I can only hope "they" heed our plea to make room for the screen room/anechoic chamber we now have. If not, someone will get it pretty cheap.

Now, can you tell me where to get a DC-90MHz (or at least down to 10kHz) amplifier with less than 5dB NF, about +60dBm output TOI (and correspondingly good SOI), capable of about +10dBm output, capable of flat, stable gains from perhaps 10dB to 30dB? Oh, and its power dissipation should be less than 5 watts for sure.

Cheers,
Tom

I think there are ways a serious homebrewer can handle this, if you can trust the IC to be linear (behave according to spec) down below some reasonable level. If you don't have access to a calibrated power meter, you can still build something that will work pretty darned well, with some care and patience.

One specific way to do this, but not the only way for sure, is to build a thermal-based sensor. You make a matched pair of 50 ohm loads, using, say, 0805 SMT resistors (49.9ohms; you can get 0.1% parts from Mouser if you need that accuracy at low freq, else just use 1% parts). Etch a board carefully so that the two are in identical environments. If you want to use this up into UHF (or above), you'll want to make sure that they are on good RF circuit board material, and fed through 50 ohm microstrip or stripline. An alternative would be to use small semirigid cable to feed them. On each, mount a tiny thermistor. Put the thermistors in a bridge circuit which is self-balancing by feeding DC to one of the loads, while you feed RF to the other. Calibrate with DC to the input; surely measuring DC power accurately for a serious homebrewer won't be a problem. If the two loads are identical, they should have identical DC feeding them; if not, look very carefully at why they aren't. The construction should be shielded from unequal ambient effects, of course. When you are satisfied that they are matched, you should be ready to measure RF...if you are confident that the return loss is low enough on your input port. (If not, spend some time building a return-loss bridge...another useful piece of equipment!) (If I spent less time on the internet, maybe I could write up a construction article on this...while I have access to some very good equipment to verify its operation.)

What is the sensitivity of such a simple device? I believe that a careful builder should be able to measure well below a milliwatt with it, likely down to 0.01mW resolution. It would be good for max 0.1W input. And I know for sure you can get better than 30dB return loss with an 0805 resistor out past 1GHz...quite useful (better than 20dB return loss) to 6GHz...though you may have difficulty verifying this

unless you invest in a precision load and a lot of time bootstrapping your measurements.

Also...I haven't looked at it for quite a while, but I know that Linear Technology used to make an IC which does just about all of what I described above. It's worth a look, for sure.

As for Analog Devices parts, I believe they've make it much easier to get small quantities these days through a web ordering service on their site.

It might be fun to start a list of recommended test equipment, and how key pieces can be homebrewed, and how to have reasonable confidence in the calibration.

Cheers,
Tom

You are burnt out (or pissed off, as we say here in VK) and its part
of what engineering types do - do you think you could handle a brain
dead job that was just easy repetition - I doubt it. If the customer
has given you an impossible job, tell them - if they cant accept that,
then why bother getting stressed over someone elses inadequacies?

This time will pass (it always does) and sometimes its as simple as
stepping back, closing the workshop door, and "going fishing" for a
few days. The alternative is to stay stuck in the doldrums so your no
good to man or beast until the situation gets so bad you wind up doing
something stupid in desperation (Sort of like saying really stupid
things (own experience) on these groups and regretting it later - like
a speeding bullet, the "post" key cant be called back.)

Slow down, step back, seek the counsel of those close to you, and let
time pass.

Hope this helps.

Hey,

The last part sounds like a real gung ho manager trying to inspire his troops. Afterall, all the engineers do all day is lie around collecting their pay. MBA's do come in handy at times and keep people inspired.

I was referring to the TRF receiver, which was used in this thread as
an example of old technology.

>Perhaps your point is that old TRF AM BC receivers are no longer very useful
>for reception today, compared to superhets, but that's another issue.

TRF is an example of obsolete technology, which is not very practical
these days.

>>Regarding old VHF/UHF receiver circuits, most of them are more or less
>>useless today, since most of them were designed to minimise the noise

Then you must be referring to sparsely populated areas such as Alaska
and some states west of the Mississippi.

>
>But even if that equipment is truly "useless" today, the reason is not because
>the equipment and its design concepts are old.
>
>Is a simple "crystal" receiver useless today?

I would consider it useless if you can not recover any useable audio
signal from it. Here in Finland, there are only two medium wave
transmitters (both used mainly by the Foreign Service), one on the
west cost (targeting Scandinavia) and the other on the south cost
(targeting Russia and Estonia). The ground wave field strength from
these transmitters falls off quite rapidly within the country due to
the low ground conductivity. I very much doubt that a crystal receiver

would give any usable signal in most part of the country from these transmitters.

However, night time sky wave long wave signal from Central Europe or Russia might give a usable signal with a tall antenna and the selectivity in the 150.. 290 kHz range may be sufficient.

>>
>>I was a bit worried when a facsimile of a radio book originally
>>published around 1950 was republished last year.
>
>What book is this?

It is a book written in Finnish by Wiio and Somerikko called "Harrastelijan Radiokirja" (A radio book for the amateurs) containing basic electronics, BC receivers, audio amplifiers and radio amateur receivers and transmitters for HF and 2 m.

>>In those old days
>>there was very little activity above 30 MHz (the FM broadcasts started

>
>Quite possible, but not guaranteed. Many old designs had surprisingly clean
>signals, because the amateur bands are not perfectly related harmonically.
>Amateur transmitters with high harmonic output would interfere with other
>services
>using HF.

One 50 W transmitter design from the year 1950 expects a crystal or VFO signal at around 7 MHz with the first 6V6 working as an amplifier and the second as an amplifier (7 MHz), doubler (14 Mhz), tripler (21 MHz) and doubler (28 MHz). For 28 MHz, the final 807 was used as a doubler (possibly by amplitude modulation applied to the anode) and as an amplifier on all other bands. Thus, on 28 MHz, only the tank circuit was resonant on the final frequency. I guess that the amount of harmonics in the VHF range has been quite high, not to mention subharmonic leakage in the 7-7.5 MHz, 14-15 MHz area, which were partly out of the lower amateur bands.

If such transmitter would be built today, it would definitively not meet the 40 dB HF and 60 dB VHF/UHF harmonic suppression requirement of current regulations.

>>When building something from an old design, you really have to

>while others were deemphasized.

This stupidity started with the desire to build battery operated
general coverage receivers. The battery consumption considerations
prevented the use of strong mixers and preamplifiers, so the IP3
intercept figures are often inadequate.

The situation got worse when the front end typically only contains
some octave wide bandpass filtering in front of the mixer (to prevent
harmonic mixing) so in addition to the desired ham band at least one
or two broadcast bands will also enter the mixer at full strength.
With dozens of strong BC signals at least in Europe entering the
mixer, the number of possible 2nd, 3rd and higher order
intermodulation frequency combinations will be huge, creating a
continuous noise floor of intermodulation products, if the various
intercept point power values are inadequate.

Adequate front end selectivity in front of the mixer will reduce the
amount of intermodulation products generated between the RF signals
(fewer combinations for intermodulation and crossmodulation) as well
as reduce the problems of reciprocal mixing of the LO phase noise
(especially keeping the strong broadcast signals out of the mixer).

I do appreciate all the input that I've received so far. It is all constructive and very positive. I would agree with all of it, had I not been exposed to what I've been exposed to in the last few years. During the 1990's I, like everyone else, was excited when things were going so well. The sky seemed to be the limit, but it kept getting better than good, that's when I started getting nervous. My employer at the time kept having "town hall" meetings saying everything was fine, but I was looking at what was going out the shipping dock and how many jobs were being eliminated here in the US and things didn't seem to match with the glowing words of the meeting. The stock price of the company was going up up up, but nothing was going out out the shipping door. The only thing I could do for myself was to move my 401K funds for stocks into the general fund. At that time, I was ridiculed by the other employees, but when good ol' XXXX took a dive and the stock fund went in the dust bin along with the 401k's of my fellow employees, somebody was singing a different tune and I wasn't feeling good about being right. I still have that "sinking feeling" and it won't go away. My generation is now in charge of the government and a major portion of corporate America. They all need to get out of the Hippy days of thinking and grow up. Sending our labour off shore along with everything else will not build a strong US, it'll only line the pockets of a few senior officers in the company. The rest of us will be standing by looking bedraggled and forlorn. I'm at a complete loss as to what to do at this point. I can control none of this.

Doesn't my message bring a breathe of sunshine into your day! ;-)

Len,

Got the Xanax years ago and also got a case of hives. Miller Lite works a whole lot better, doesn't cost as much and tastes great. :-)

BTW, if you think working at the low end of S band is bad, try 136-172 MHz. This band is for people who want to bang their head on the wall and even enjoy it.

The original topic was about RF/oscillator tracking, which is only relevant to even older single-conversion designs with a 455kHz IF. These went out of fashion because the image rejection at the high end of the short-wave band is very poor. As soon as HF xtal filters were introduced, single conversion to 455kHz became obsolete technology for HF receivers.

It's still valid for MF/LF receivers, though, so OSCTRACK does have its uses. If you're into retro and restoration, OSCTRACK would also be an interesting way to check the original design calculations that were done with charts and slide-rules... but not if your restoration ethic forbids you to improve the original design ;-)

Front-end preselection will help, up to a point, but when you're using the European 7.0-7.1MHz band it won't do anything much to keep out the one-hop megawatt broadcast signals - they start right in at 7.1MHz. There have been designs for helical filters that will help, but at HF they may be as big as the rest of the receiver.

Even a super-sharp preselector is no substitute for a strong (= robust / bomb-proof / high-IP3) mixer. Ideally you need both, but the mixer comes first because it needs to resist IMD between close-in signals that no LC filter can possibly separate.

Thanks for all the replies, I chose the word 'condenser' instead or
capacitor, because it sometimes has better effect to use the
inaccurate words, and also for fun

I maybe wrong in this matter, but believe that even for HF it is no
advantage to use 50 ohm feeder system for high impedance antennas, and
G3LDO mention that he worked 80m DX from his car using halfwave (40m
long) verticals, then the ground losses were very much reduced

The reason for choosing capacitors is to build a different antenna
tuner, where impedance is transformed down to a lower impedance to
suit the RX and TX, but the antenna is fed from a high impedance line.
For an antenna impedance of several thousands ohms, even 50 ohm ground
losses shouldn't add much to the total loss

AM-6155/GRT-22
Linear power amp, 225-400MHz, 50W out (conservative) 10W in, Eimac X651Z/8930 final, extensive metering, can be converted to 116-150MHz, rack mount 7" high, 80 lbs, ITT (model 3212), Part of AN/GRT-22.

This Amp uses Emiac X651Z/8930 in silver-plated cavity-drawer; 175-turn TUNE counter dial. Main chassis has solid-state power supply and buffer amp/mulitplier; panel meter monitors voltages. Requires 105/120/210/240 VAC 50-400 Hz and +20 V req 60 ma. +20 V keyed; 7x19x18.5, 80 lbs shipping weight.

The HV Supply from AM-6155 is Loaded with GREAT parts to include a 1752V at 270ma transformer, 8HY 300ma choke, 100K ohm 95 watt resistor, 2x5mfd 3KVDC capacitor, & rectifier circuits card.

One ham has used a 4CX400A (available from Svetlana)to raise the output power to 450 Watts. Others have reported that you can run the 8930 (electrically identical to 4CX250R/7850W) at about 400 watts on 432 Mhz...

a quick search kicked out plans to use the amp on 144, 220, and 431 MHz as well as other mods..

Used - Excellent Condition (NOT TESTED) $295.00 plus shipping from zip 31088.

Email if you have any questions or would like to make an offer!

OK

But my answer to "does anyone design this type of receiver" was about
capacitor-tuned superhet receivers.

I don't think TRF is obsolete ate all - at least not for some applications,
such as MF/LF work. In fact, new components like high Q inductors make TRF
designs more attractive for some applications.

Actually, it refers to much of the USA outside the major cities.

>>But even if that equipment is truly "useless" today, the reason is not

This is the main point. Merely being an old technology does not make something inferior, useless or obsolete. And merely beng new does not make something superior.

So with an adequate antenna, it's not useless at all, despite being truly ancient technology.

OK.

Here in the USA, there used to be a magazine called "Ham Radio", which is now defunct. Publication of new issues stopped in the 1980s, as I recall. Although it was a small magazine of limited circulation, it was well regarded by US hams because of its focus on technical issues and homebrew projects. many US hams still miss it. Recently the entire series of magazines became available on CD-ROM, priced at $150.

Possibly, but without measurement it's not certain.

It probably would not meet those specifications on 10 meters, if used without
any additional filtering. But on the other bands, it may meet those
specifications, or exceed them. It all depends on the exact design, and how it
is applied.

Do you think that all of the transmitter designs published in "Ham Radio" would
meet the modern -40 and -60 dB specifications, on all bands?

Agreed - but again the experts and professionals of the time told us that these new designs were superior to the old LC manually tuned designs. They said we were living in the past when some of us wanted narrow filtering before the mixer.

That's only true for signals far removed from the desired one. When trying to receive a weak signal closely surrounded by strong ones, you need a high-performance front end.

Refrigerator magnet prayer ... regarding the things that can and can't be changed and the wisdom to know the difference.

Good advice. Wayne the story about the work situation is interesting as years ago I gave a talk to a group of Scouts about my profession in health care. I then visited a popular "watering hole" where business types gathered. The overheard conversations made me sick ....they dealt with how the competition was going to get screwed by really devious means. Thank God I was in the noble health care profession and above this crap. Our patients came first not screwing the fellows in the hospital down the block. Fast forward 15 years. Hospitals started to advertise .... HMO's were starting at the bid of our "noble" government. "Suits" started walking about with greater regularity. Budgets were cut ....workloads increased and our product was not one of improved patient function but one of fancy advertised programs and beautifully bounded and organized "Quality assurance" manuals. Fast forward 15 years ... the circle is complete. Health care is in the hands of the big guns who routinely screw the competition. There is precious little I can do about this save direct my energies to my patients.

I am going out to run my 6 mile loop now. It is a crisp Sunday afternoon and my thoughts will go the sights of the fall foliage and how good life is once some of the crap is flushed away.

To clear up a point, "TRF receiver" refers to a tuned detector with
a tuned RF amplifier ahead of it. Technically, any superhet with
a gang-tuned RF amplifier and LO is also a TRF. :-)

Reg Edwards' nice little program is well-executed. [anyone who
has actually done program writing will understand that] The thing
about it is that it is a good, quick solution for a problem that is
rapidly disappearing.

>>Perhaps your point is that old TRF AM BC receivers are no longer very useful

Offhand, I'd say an old (non-superhet) TRF receiver was impractical
a half century ago! :-)

Irrelevant to LO tracking of RF in superhets, especially so in the most
populous state in the USA, California, quite west of the Mississippi.
:-)

A "crystal set" is good for one practical application: A field-strength
indicator at a home station. It is just an unamplified diode detector
good for checking AM or RF carrier presence. Some folks carry so
much emotional baggage from their first personal experiments in
radio with "crystal sets" that they lose all rational connections to its
technical facts.

A small reminder: F. Langford Smith's "Radiotron Designer's
Handbook" has been reproduced on CD by Audio Amateur
Publications, Inc., Peterborough, New Hampshire, USA. This
PDF collection seems to come from one of the last of that
excellent Australian handbook printed on paper in the 1950s.
It is strictly for vacuum-state enthusiasts (or for memorabilia
as in my case). Yes, it does have the LO-RF tracking equations.
:-)

Some broad, careless sweeping generalizations going on here!

Every single piece of electronics ever built for any reason contains COMPROMISES. Once that is accepted (it should be since it is reality) then one can talk about technical considerations and design problems. "Homebrewed" radios have all kinds of compromises...not always for technical reasons.

With some effort, any designer can put together a receiver front-end with an IP3 of at least +30 dbm, using Schottky mixer diodes and a very high level local oscillator injection (I've done it at work). The same designer can also go to the food market in a 2 tonne truck to bring back six bags of groceries that would fit into a little Opel City hatchback. The choice is personal, not technical.

>The situation got worse when the front end typically only contains
>some octave wide bandpass filtering in front of the mixer (to prevent

>intermodulation frequency combinations will be huge, creating a
>continuous noise floor of intermodulation products, if the various
>intercept point power values are inadequate.

Okay, then here's a chance for the amateur radio designer-homebrewer to roll their own using sharp-enough skirt selectivity front-end bandpass filters (per band) to attenuate the adjacent bands. Make the first mixer with a high IP3 and watch stage gains and levels to the second mixer to avoid adding to the intermodulation problem. Tuning is done with the second LO, the first LO being fixed per band. No tracking of LO with front-end RF stages needed at all. HF bands are all narrow enough to allow that, even 10m. That principle has been around and working well for over four decades. Details are in the individual stage gain values and individual intermod capability of those stages.

In US Army service in Japan in the 50s I acquired a nice Hallicrafters portable general coverage receiver using "battery tubes" (1T4, 1R5, etc.). Trying to use it for DX at the corner of a 2 KM x 1 KM antenna field radiating about 300 KW total over the 4 to 18 MHz HF spectrum was not a good thing. :-)
At a 10 KM distance the receiver worked reasonably well.

>>As another example, many designs using synthesizers suffer from poor
>>phase-noise performance compared to older designs using LC and crystal
>>oscillators.

A nonsense generality. In order to make that generality true, the "LC and crystal oscillator" (of older designs) phase noise has to be MEASURED and used in comparison. Phase noise measurement and quantification is a relatively recent thing and was rarely, if ever, done with tube architecture radios. Phase noise affects QAM signals' demodulation and modulation far more than CW or SSB signals. It is

the hunt for minimum BER in these digital times using various
constellations of QAM with minimum RF levels at the transmitters.

Any reasonably-good PLL design of a synthesizer will exhibit RF
output purity as good for amateur radio use as any "older" LC or
crystal oscillator. "Reasonably good" refers to proper loop filter
calculation and normal attention to supply rail decoupling. The
advantage to PLL is the ability to produce hundreds of individual
frequencies, all crystal-locked, without buying the same number
of individual quartz crystal units.

Direct digital synthesis (DDS) has various forms, including the
"fractional-N" type, all of which may be subject to greater spurious
output than the simpler PLL. There's been a lot of work on that in
the last decade and enough body of knowledge to steer the
designer in better ways to implement them.

>>End result is that under modern-day HF amateur receiving conditions, some
older
>>designs will outperform newer designs of equivalent cost and complexity.

The "end result" of that statement seems to be that some don't
want to give up their cherished notions of old equipment. :-) :-) :-)

>Adequate front end selectivity in front of the mixer will reduce the
>amount of intermodulation products generated between the RF signals
>(fewer combinations for intermodulation and crossmodulation) as well
>as reduce the problems of reciprocal mixing of the LO phase noise
>(especially keeping the strong broadcast signals out of the mixer).

Ulrich Rhode pretty well summed up receiver performance and design
criteria over a dozen years ago. See his book on the subject and the
special issues in the last issues of Ham Radio magazine. You need:

1. High IP3 in the mixer...which means a higher than normal LO level.
2. High IP3-equivalent in any RF amplifier ahead of the mixer (if used),
something that is not too swift with variable-gain tubes but better
with Gilbert Cell ICs...presuming AGC is applied to that stage.
3. Be careful with stage gain values to avoid overdriving following
stages and having them create intermod problems.
4. Distance from in-band SW BC transmitters. There just isn't any
way out but distance for the strong, local in-band 40m stations,
unless you want to build high-Q tuned cavities the size of a room.
A large room. Very large.

3369. How can you screw up a Dummy Load?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-10-27 20:03:55 UTC
From: Dave <local_42remove@hotmail.com>
Message-ID: <LEXu9.131629$zE6.459703@rwcrnsc51.ops.asp.att.net>
Source record: 40431

Subject line says it all. Finally broke down and bought myself a decent soldering station and figured I'd whip up a dummy load for my first project. What can be more simple than a chaises mount UHF connector, a couple pieces of scrap copper board, and a hand full of resistors?

Cut the board into two pieces 2" x 2 1/2"

Soldered each of the resistors to the boards. Used (20) 2W flame proof carbon resistors rated at 1KOhm 2%.

I read 47 Ohms on the board. By eliminating 2 of the resistors I have 49 Ohms.

Great I say, I'm with in 2% of my target resistance. Plug her into my meter and calibrate the meter to read SWR and I read a whopping 10!!!!

What am I not understanding about the simplest piece of equipment in my shack? Anyone out there give me a clue as to what I might have done wrong? I know the standard carbon resistors aren't the best for a dummy load (something about inductance right?) But from what I've read they should work fine for my purpose, and with my limited knowledge of electronics I need a push in the right direction. Very few web sites seem to talk about dummy loads (can't blame them, how much do you need to know about a bank of resistors?)

Dave

There's a big part of your problem. You need to find a company that makes actual products, not one having stock as its main product. Believe it or not, there are a lot of companies out there that really do make money by building and shipping products.

Looks to me like your world view has gotten distorted by being in that environment. You need to get out of it.

Hi Gary:

I have the GR-78 and a manual but no battery. According to the
schematic each side of the battery has 4 cells and the output is 9.6 V.
One can make up an 10.8V external supply. D-503 in the receiver will
drop the 10.8V to 10.1v for proper operation. Let me know if you get
your GR-78 up and running. May have a go later this winter to get my
GR-78 going.

I'm sure one could you D cell rechargable batteries to put the receiver
back to it's orginal state. As far as I can find out the Heathkit cell
used is no longer manufacutred by anyone.

Source record: 40435

Hi all,
I am collecting parts for a homebrew amplifier and have 2 encapsulated diode rectifier "blocks".
They are labelled as:
STC (manufacturer?)
484 LFU 30 D
EHT 1500 B
and hand written in a panel they both carry "A66"
They appear to be of the "doubler" design carrying a "+", "C" and "-" each.
Both are mounted on ceramic stand-offs onto a plate. Each encapsulation measures (approx) - 200mm long x 32mm wide x 30mm high. The stand-offs lift the bottom of the encapsulation approx 25mm + an integral 5mm mounting post (?) = 30mm plate to bottom of encapsulation.
I believe them to be from a fairly old piece of army equipment.
Does anybody have an clue as to their true ID and or ratings, please?
Thanks for any help you are able to give.
73

Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.swap,rec.radio.swap,alt.radio.pirate

I'm selling BA1404 chips for $5/ea ppd. These chips are the heart of many low-powered FM transmitter kits. There are a number of plans available online, as well as on the data sheet, to build your own low-power radio station. It'd be great for a weekend project or science-fair/Boy Scout-type project. I built a transmitter and use it to send MP3s and "internet radio" from my PC to the radios in the living room and bedroom (MP3s and foreign stations on a clock radio -- nice!).

Please visit: http://www.radiochips.com for details and ordering information.

Thanks!
Jeff

Quite so... which implies that something you said above is actually not
correct.

For a start, are you sure that the resistors really are carbon, of
reasonably low-inductive construction? File one open and check.

You don't mention the frequency, but it's hard to imagine that any
reasonably low-inductance construction could give you and SWR so high at
any frequency below UHF... not with 18 resistors (and inductances) in
parallel.

Next stop is the SWR meter. Does it read a low SWR with your antenna, or
any other known good load? Check it again.

It pretty much has to be one of those three.

Actually carbon composition resistors are what would be desireable. Not
carbon-film, though. They are the ones that have some inductance.
I think those 2w, 2% flame-proof guys might be carbon film. If you're
in doubt you can dissect one.

After reading your replies here are the answers to questions asked of me and ultimately what appears to be the little problem I overlooked.

1q)For a start, are you sure that the resistors really are carbon, of reasonably low-inductive construction?

1a)You know to be honest when I picked them up I made an assumption. I'll double check the resistors first thing.

2q)You don't mention the frequency, but it's hard to imagine that any reasonably low-inductance construction could give you and SWR so high at any frequency below UHF... not with 18 resistors (and inductance's) in parallel.

2a)Well OK, 10/1 was an exaggeration. Just put her back on and I'm reading a little under 5. Still WAY too high.

3q)Next stop is the SWR meter. Does it read a low SWR with your antenna, or any other known good load? Check it again.

3a)I read 1.2/1 with my antenna hooked up. Double checked and everything reads just as it always has. I have a known BAD meter and it reads 1.5 with the dummy load.....Then again it would read 1.5 if you dunked it in a pail of gasoline.

4q)What frequency is being used for the SWR measurement ?

4a) 27.275

5q) Actually carbon composition resistors are what would be desirable. Not carbon-film, though. They are the ones that have some inductance.
I think those 2w, 2% flame-proof guys might be carbon film. If you're in doubt you can dissect one.

5a) Doh! Metal film not carbon. I suppose I should look more closely at what I pick up. Like a kid in a candy store I walked outta there with duplicates of some parts and equipment and now I see I didn't grab the resistors I thought I did.

6q) If you could send me your valid email I'd be happy to discuss the matter.

6a) I can be reached at local_42@hotmail.com Feel free to write me despite the fact I think I've found the culprit. It's always nice to hear from good people about interesting things.

7q)What frequency were you using ? - It might work for HF but I wouldn't like

to try it on VHF.

7a) See 4a. Please refrain from commenting on the band. It is hard enough not to randomly defend my status for no apparent reason. I am enjoying my self though!

It appears I was in such a daze grabbing components and equipment, giddy even, that I wasn't paying close attention to what I bought. This would also explain why I walked out of the shop with multiples of the same iron tip and a few for the wrong style iron. Been a long time since I was so excited about home projects. Now that I know what the next step for my dummy load is, I can start putting together my antenna switch and from there I have a giant list of "must build" projects. Thank you for the nudge in the right direction. We'll see what happens when I put some real carbon resistors on my board, sure to be a much more pleasant result.

Dave

My experience is that carbon film resistors have negligble inductance (i.e., very much less than the resistance) up to a frequency where the physical length becomes the limiting factor. Does anyone have measurements that demonstrate otherwise?

How about HF receiver designs with higher IFs? For example, the HBR receivers and many Hallicrafters designs use first IFs around 1600 kHz. The National NC-300 and -303 use a first IF of 2215 kHz. All use ganged variable capacitors in the front end, and the high, fixed first IF for improved image rejection.

>As soon as HF xtal filters were
>introduced, single conversion to 455kHz became obsolete technology for
>HF receivers.

I wouldn't say "obsolete". For frequencies up to about 10 MHz, a single-conversion 455 kHz IF design has adequate image rejection in most cases if an RF stage with high quality tuned circuits is used.

I have a pair of Hycon Eastern filters (2215KA and 2215KB), acquired in a trade some time back. Center frequency 2215 kHz, 6/50 kHz (not a typo - they are spec'd that way) bandwidths 250/1000 and 2800/8000 Hz. They are commercially-made filters aimed at the amateur market, and are NO - about 40 years old. They cost $44.50 each back then - and you needed a different filter for each bandwidth desired!

>It's still valid for MF/LF receivers, though, so OSCTRACK does have its

>you to improve the original design ;-)

HAW! That's a good one!

Perhaps OSCTRACK would help in my design of an HF receiver using the Hycon Eastern filters. To cover 3.5-4 Mhz, the VFO would need to tune 5.715 - 6.215 MHz.

'zactly.

On this side of the pond, things can be quite challenging, too. The US power limit is 1500 W peak output, and with some antenna gain a high power local can make quite a bit of noise. During contests, hams in high population density areas find it's not unusual to encounter several very strong local signals only a few kHz away from the weak desired signals. Front end preselection capable of rejecting all but the desired signal just isn't practical. What's needed is a front end that has both a low noise figure and high dynamic range, followed by an IF that has as much selectivity as possible right after the first mixer.
>
>Even a super-sharp preselector is no substitute for a strong (= robust
>/ bomb-proof / high-IP3) mixer. Ideally you need both, but the mixer
>comes first because it needs to resist IMD between close-in signals that
>no LC filter can possibly separate.

Exactly! And the selectivity (in the form of an HF xtal filter no wider than the mode in use requires) should be right after that mixer. Dual conversion designs that upconvert to a wide filter at VHF (most "modern" HF ham transceivers), or that use a tunable first IF (most vintage HF ham transceivers, such as Heath SB series, Yaesu FT-101 family, etc.) are simply second-rate by comparison. That's why the Ten Tec Omni, Elecraft K2 and Drake R-4C perform so well in the QEX analysis cited earlier. They are all designs that put excellent selectivity right after the first mixer.

Mike,

I got laid off by Moto for 1.5 years. I was ready to go backto work. I
just wonder how long this will last. I wish you would start looking
around and tell me where I'm going wrong. I don't think that rf jobs will
be here for native born engineers in the 48 state US for much longer.

Your impedance is not all resistive. There is a reactive component as well. This can not be measured at dc with an ohmeter. You do not mention what frequency your transmitter is on. There could be enough inductance in the resistance bank to be a factor. Try at your absolute minimum frequency and see if results are the same. (Have a 160 mtr rig?).

Also, dont overlook the connector cable and it's connections. A piece of braid across the line can wreak havoc.

I did some physical calculations once on a regular carbon film 1 watter at about 10k and yes indeed the inductance is in the .0xx uh range, substantially less than what might be considered normal lead dressing. How this may or may not factor into the bad dummy load mystery is still unknown as I'm waiting to hear what freq range was used. If its HF I wouldn't blame the resistor inductance (unless they are in fact wirewounds).

Good old 2 watt carbon composition resistors can be a bit tricky to
locate these days but this site claims to have 'em. Since they are NOS
they may have drifted upwards in value...maybe not.
http://hometown.aol.com/maryann003/page6.html
Let us know how this turns out. I'm a little amazed that the resistors
you used would screw it up as bad as it seems they did on an HF freq.

I don't have the QST article handy, but there was an article
about a solid-state weather warning system in 73 for September 1974.
At a glance, it seems similar to the QST article, but since I haven't
looked at the latter recently, I can't say how similar a scheme the
two articles use.

I grabbed the wrong stack in my haste. Had to turn to the manufactures site
to see they were Metal film. Not even carbon film let alone carbon.

> You don't mention the frequency, but it's hard to imagine that any

> any other known good load? Check it again.

Meter reads 1.2 on the Antenna. I'm sure the meter is accurate. At this
point I definitely rule out the meter as a possible cause. My follow up post
below says all this stuff. I'm picking up the right resistors tomorrow and
I'm sure this will solve my problem.

I appreciate the response. I should be a bit more careful when picking up
parts. I act first and think second some times, hehe.

Are you implying that the only reason our colleges and universities teach much in the way of RF/Microwave fundamentals is so a student can better understand things like standing waves and mutual inductance for his/her digital circuit boards to reach 3-6GHz clock rates?

The inductance can be calculated by scraping the paint off and measuring-up the diameter, length and number of turns in the helix. No great accuracy is required because, as Roy says, the inductive reactance is usually negligible compared with the resistance.

For 50 ohm dummy loads made by connecting several higher-value resistors in parallel (to increase the power rating and reduce the effects of the inductance) I've found that 1k 2W metal film resistors give about the best combination of resistance, inductance and power dissipation.

That worries me. I assumed my problem was the Metal Film resistors. Leave it to me to screw up the single easiest project on earth. There must be something really stupid I'm overlooking. I'll just whip up another on Tues. and this time pay very close attention to construction technique and materials, I guess.

Hello Dave,

Got same problem here, dummy load not useful above 30Mhz (because of
resistor's type I think)
Also problem with SWR meter (home made and not precise/balanced)
Another problem was a big mess with cables and for some time I was
reading the SWR on the antenna not on load :)
Now is ok, I connect an "calibrated SWR meter" and I don't use the load
above 30Mhz.

Using a mangled email address is a good prevention from becoming the target of the spambots but it is always a good idea to end your message with "Remove the obvious for valid email address" if you are expecting a direct reply.

On the other hand, if I go to reply to a posting and see an address suich as abcSpammersShouldBurnInHellWithTheirMothers@xyz.com..... I can usually figure out what to do. :-)

Indeed - I work for Analog.
You do not have to invent a company name as such - the facility is
deliberately designed to also support home constuction. I confirmed
this over a year ago on behalf of an amateur who was writing up a
homebrew project for a magazine.
Also , once you have filled in all the online details, you do not have
to fill them all in again on a future visit when you want (up to 2 of)
another IC - so it's easier on subsequent occasions.
A good part of the website to check is www.analog.com/RF as well as
www.analog.com/DDS . I believe " /logamps" works as well.

http://www.aade.com IIRC. They have a meter for this stuff.
Radio Sh** have a book on using your VOM for many things,
including inductance.

I got both, the book first, and the meter when I couldn't
get the book straight. Then after I used the meter, I understood
the book better, and was able to use a VOM for inductance in
heavy stuff.

I heartily reccommend the meter. You can get it in a kit, but I
got it ready to work, because of my own time constraints.
Mine paid for itself the first evening I used it on a RCX I built.

You might try to get one of something like that, and see if the
reactance of your load is too high. You might have cap trouble
between the coppere plates.

And in future, you will then be able to test each element and
module of the project. Much improve your chances of success
on any project.

Seeing the word 'remove' in the address is also a pretty good clue. But
some folks don't have their news reader set up to actually see the email

There was a request about a week back asking about PCB software,
unfortunatly I just acciudently deleted it.

PCB (currently v1.6.3) is a program for designing PCBs (surprise)
under the X-window system (e.g. Unix (including Linux, Hp, Solaris,
etc. but NOT M$ Windows) and is issued with no charge under the GPL
licence.

Home page is at:

http://bach.ece.jhu.edu/~haceaton/pcb/

taken from home page is:

FEATURES

Multi-Layer: Up to 8 layers plus silkscreen
Parts Libraries:
TTL 74xx
connectors
crystals
linear series
voltage regulators
resistors: discrete and arrayed
capacitors
transistors
PALs
LEDs
RAM ICs
easy to generate user-defined parts
Output formats:
PostScript
Color for design checking
B/W for mask generation
Gerber (RS-274X)
Output layers:
up to 8 routing layers
component mask
solder mask
silkscreen(s)
drill file(s)
solder paste
Design Rule Checking (DRC)
Complex ground/power planes
Show electrical connectivity
Netlist comparison

Drill report

Hope this is of help,

I have not tried this yet, but could you try laser printing everything
onto clear plastic (like for an overhead projector), and securing it
to the panel. You would then use an Exacto to cut out any holes
needed.

An advantage of this would be being able to work through revisions on
paper until you get it right, and that it would be one piece.

Happy trails,

I'd be more than interested in a good, no-mess silk-screening set-up. Using
etch-resistant ink would be a great way for making small runs of PCBs, as
well as being able to print component overlays.

Steve

My old Reference Data for Radio Engineers 5th edition has a table that
compares various rectifiers. It lists a typical forward drop of 1
volt per cell (plate) for selenium rectifiers.

Hm, I remember that when replacing a selenium stack with a modern diode, a resistor was put in series with the modern diode. The value of the resistor, as I recall, was determined by the number and area of the plates in the selenium rectifier. If no one recalls how to determine the resistor value, someone can probably find it in a handbook from somewhere in the '60s, or one of the books on converting World War II surplus equipment that were common around that time. The resistor value and an estimate of the radio's current drain will get you the drop.

Hi Rob,

What I would suggest for a first antenna is.......

The general dipole as long as you can make it, and as high as you can make it, using twin lead and a tuner.

This is a simple setup, works on multiple bands, and in fact works pretty well.

You'll probably gets lot's of different answers on this, but I doubt you'll get much better an antenna.

Later, if you want to make something for one particular band, or want to chase DX, you might think of installing a band-cut dipole, or a vertical. But in the meantime, you still have a very good antenna, and can experiment with the others in leisure.

I recall 2-3 volts PER SECTION being typical of a selenium rectifier.
As Roy says, it might be easier just to estimate the current and choose
the resistor accordingly since the 1N400* are predictable.

==========

A little arithmetic will tell you what the volts-drop is across your particular rectifier sample. You already have the DC output voltage. Now measure the AC input volts to the circuit . . . .

It's the peak AC volts you are interested in.

Peak Volts = Sqrt(2) * RMS volts, as measured on your AC voltmeter.

There will be 2 volts or less across the silicon bridge. You can forget it.

There will be far more volts drop in the transformer windings. For a guide measure the DC winding resistance and multiply by the peak current. And don't forget the primary winding. Peak transformer currents may be as high as 5 or 6 times the DC load current at full load.

You will find an appreciably higher DC output voltage using silicon diodes. With a large smoothing capacitor and a 250 V RMS transformer winding it may soar to 250 * Sqrt(2) = 350 VDC. Less volts drop in the transformer at peak current.

What I remember most about selenium rectifiers was the horrible smell when one burnt out - which they often did ! The smoke could have been used as a nerve gas - a weapon of mass-destruction.

Did you actually read that paper ?

It lists three separate R-4C versions, two original (one with tube,
the other with FET second mixer) and a heavily modified. Some
parameters of the original versions were even worse than those of the
Icom IC-751A.

It was not clear at what bandwidth the noise floor of all the
receivers were measured, which affects the IMD DR.

The heavily modified R-4C contained new mixers, extra amplification to
compensate for the losses in the new mixer and also contained a 600 Hz
filter, which drops the noise floor and larger dynamic ranges can be
quoted. Claiming that this excellent performance is _only_ due to the
good original design (although a clean oscillator definitively helps).

>The Elecraft K2 is a low-cost single conversion design, yet it compares

I assuming you are referring to diode ring mixers like SRA-1H, which require +17 dBm (50 mW) of LO power and which has a 6 dB loss/noise figure and also assume that the +30 dBm is output (not input) IP3.

Some calculations can be made of the expected performance. Assuming IF amplifier noise equivalent noise floor in the SSB bandwidth of -135 dBm (including diplexer and filter losses) two undesired mixer output signals at -25 dBm, the mixer 3rd order products would be at -135 dBm, so the ultimate dynamic range in the SSB bandwidth would be 110 dB.

Converting these figures to the mixer input, the offending tones are at -19 dBm (25 mV or S9+54 dB) and intermodulation products an noise floor at -129 dBm (0,8 uV). Assuming 10 dB SNR, the sensitivity would be about 2,5 uV.

Interfering signals can be stronger than -19 dBm, thus, the IMD dynamic range will deteriorate rapidly. Alternatively the strong interfering signals can be attenuated to -19 dBm, but this deteriorates the sensitivity my the same amount. Is this relevant depends on band noise level.

Of course you can manipulate the dynamic range figures e.g. by using a PSK bandwidth, thus the noise floor will drop, the intermodulation products can be dropped to this level by dropping the offending signal levels relative to the IP3 point.

The third order intermodulation question is very relevant when a large number of offending signals can produce intermodulation of m*f1+/-n*f2 falling on the _desired_ receiving frequency. This is typically the situation when a large number of strong signals are allowed to enter the mixer (e.g. one or more broadcast bands). Thus, it appears as if even +30 dBm IP3 is not sufficient if very wide input filters are used.

However, the question of an multi-multi contest station with multiple transmitters and antennas are on the same site is a bit different. There are only a very few, but very strong signals at the receiver input, but the likelihood of generating 3rd order interfering signals of 2f1+/-f2 falling on the desired receiver frequency is quit unlikely and can usually be avoided by coordination between the operators.

Thus, the previous 3rd order analysis is not very relevant for this situation. However, 5th and higher order products can be strong enough to be above the noise floor.

However, on such contest sites, transmitter oscillator phase noise directly and the reciprocal mixing of the transmitter carrier mixing with the phase noise of the receiver LO and the receiver blocking will cause the most problems.

With only one signal on each band (as the contest rules usually only allow for a multi-multi contest station) the problems can reduced with high power bandpass filters (installed between the rig and the linear amplifier). Such filters were described a few years back in the QST and help to reduce both the transmitter phase noise to other bands and reduce strong carrier signals from other bands that could cause desensing or reciprocal mixing with the receiver local oscillator.

In such situation, the IP3 level is not so relevant.

It'll be difficult to get a good answer here because for most hams antennas are multiple trade-offs. The best compromises for you depends on how you want to use the antenna and what kinds of restrictions you have at your particular location.

All else being equal, a vertical will give you more low angle radiation and perform better for long distances. A horizontal dipole will have more high angle radiation and be better for closer in work. The problem is that things are not usually equal and that affects your choices. 1/4 wave verticals need a good radial system. Radials need to be 1/4 wave long. Your 6-foot or even 15-foot long radials won't do much on 80 meters. As a general rule, the lower in frequency you go, the more problems you are going to have getting a good low resistance ground for your vertical.

Any antenna that is physically short will require a loading coil to bring it into resonance. Loading coils equal resistance and loss. The farther from the feed point you place the loading coils, the less the loss. Loading a vertical at the base gives you the most loss in the loading coil. Moving the coil higher up on the antenna reduces the loading coil loss.

As someone suggested, a dipole with open-wire feeders and a tuner is a good general purpose, all band antenna. The problem you may experience here is that to be effective, the dipole must be at least 1/2 wave long on the lowest frequency you intend to operate.

Agreed. Did you see what the modifications were? Replacement of the pentode
mixer with a modern diode mixer was one big change that made a lot of
difference. Use of aftermarket filters was another.

All of the changes to the R-4C were things that were available to the designers
of the other rigs.

>Claiming that this excellent performance is _only_ due to the
>good original design (although a clean oscillator definitively helps).

The point is that the design is NOT extensively changed from the original. The design philosophy (single conversion, premixer LO generation, selectivity as close to the antenna as practical) was not changed at all.
>
>>The Elecraft K2 is a low-cost single conversion design, yet it compares

>Yes, this seems to be a very good modern design.

But - the K2 is a single-conversion design, using a fixed first IF of 4.915 MHz! It also uses a low-noise PLL in the LO. The K2 LO is relay-switched (latching relays) and operates in the HF range (~ 6 to 25 MHz). It is probably the simplest and least expensive of the current-production rigs tested.

Hi Jan-Martin,
an interesting construction was published at
http://hamradio.online.ru/cap2.htm (in Russian - sorry). It might be
made even more simple: rotor from a glass or plastic tubing approx. 50
- 100 mm dia, with alu or copper foil glued inside. Stator from a
piece of sheet metal, formed to touch the outer surface of the rotor.

Seems to me TRF is one good way to provide adequate front-end selectivity.

<< Will use 4x 1N4006 in the new supply >>

Jan-Martin-

You also need to consider whether the 1N4006 reverse voltage is adequate.
Isn't that a 600 volt diode?

When an individual diode is reverse biased, the peak voltage is equal to the peak AC value plus the voltage on the filter capacitor, which might also equal the peak AC value. For rough estimate, measure the AC voltage to the bridge and multiply by 3 (actually 2.83). Then add a little for surge protection.

To evaluate that for practical applications requires thinking of Q and a
band's bandwidth...and tracking error even with equal-section ganged
variable capacitors...plus where the offending signal is located in
frequency...and the intermodulation characteristics of any active
devices ahead of the first mixer. All of those things go into selection
for adequacy.

A thing to avoid in consideration is the "it was done this (whatever)
way before" nostalgia bias which is emotional, not logical. Electrons,
fields and waves have absolutely no human bias.

The older multiple-gang receiver structures were very impressive from
a mechanical standpoint. Relative to other receivers of the same era,
the more variable gangs, the more "powerful" it seemed. A surplus
military DF receiver in my high school electric shop seemed the
"ultimate in sophistication" when it had FIVE gangs! :-)

Perhaps the most awe-inspiring (to the uninitiated) is the Collins Radio
military R-391 receiver when it is in the automatic selection cycle
of preset frequencies. All sorts of movement, motion as the ganged
inductor cores tune over their own octave ranges, odd-shaped cams
turning at different speeds. Fun to watch the first few times. However,
there is a reason for all of it and that is related to the overall mission
specification of the receiver: general coverage at any frequency from
MF through HF with a resolution of 1 KHz.
It doesn't have "bands" as such, just inductor tuning over
approximately an octave (or 2:1), the choice of variable inductor over
variable capacitors a compromise of parallel impedance better than
variable capacitor tuning over a 3:1 frequency range versus the ability
to wind slug-tuned inductors for linear positioning of resonant
frequency. The whole 390 series were the first of the "digital tuning"
radios thus everything (including the front-end TRF) in tuning related to
linear-frequency positioning. The linear-frequency inductance change
was better than trying to achieve the same thing with linear frequency

change variable capacitors. The latter would require even more space and mechanical complexity...and higher cost with a lower MTBF. The actual tracking of the tuned RF sections ahead of the 390 series' first mixer to its first LO is poorer than with an equivalent variable capacitor (by personal measurement of several) and is very roughly equivalent to two isolated parallel L-C's response having a Q of about 25 to 30. [on HF above 4 MHz, not meaured below that] However, the "first IF" range is at a greater frequency distance, so much so that conventional tracking equations (for ganged capacitors) cannot be used and the resulting mix products with lower IP3 values do not affect operation all that much. About the only thing suffering is sensitivity, in the 3 to 5 microvolt range on HF for 10 db S:S+N on AM.

For receivers having small-percentage bandwidth band selections (not general-coverage), selectivity can be done quite adequately with fixed-tuned L-C RF sections on HF...and on up to VHF and UHF. Some quick calculation with tuned circuits will show that Qs of 40 or so don't NEED to be trimmed by any variable, either L or C. Out-of-band selectivity will remain nearly the same whether or not the L or C is trimmed/tuned over small-percentage width bands.

All the selectivity ahead of the mixer will be to no avail if the active device in the RF amplifier has low equivalent IP3 due to intermod problems of its own. On the other hand, eliminating an RF amp will reduce sensitivity; first mixer conversion is at least -6 db using a high-IP3 diode mixer. Just one more compromise to consider.

If the whole purpose of the TRF was for far-off resonance selectivity, that can be accomplished in several ways and aren't necessarily aided by gang-tuning or with tracking of RF with the LO.

>require +17 dBm (50 mW) of LO power and which has a 6 dB loss/noise
>figure and also assume that the +30 dBm is output (not input) IP3.

For other readers who may be confused by terms:

IP3 or Third-Order Intercept is really a graphical construct based on
output as a result of 2nd harmonic plus/minus fundamental of the
inputs. I say "graphical construct" since the IP3 is an intercept of
the "normal" slope of fundamental input frequencies' mix levels and
the steeper slope of 2nd harmonic plus/minus fundamental products
from inputs. For the steeper slope, either input can have the 2nd
harmonic content such that the sum/difference with the other input
results in the mixing product.
The intercept point (IP) is equivalent to either input being at the
level indicated. The graphical plot is X-Y with "RF input" on one
axis and "LO input" on the other axis. Actual output levels versus
input will depart from a straight line rather well before reaching any
IP3, a result of compression in conversion due to many other
factors. As a rule of thumb, linear input versus output will happen
from nothing on up to 20 db below the IP3. Since the compression
in conversion varies due to many factors, the graphical intersection
(the intercept) is easier to see than just looking at tabulated
numbers. It is just the intersection of the slopes of the two curves.

====

In my high-IP3 task, the LO power was slightly more and the high
input level roughly 15 db below 1 Watt (+30 dbm). Conversion loss
at low levels was between 7.7 and 8.0 db...not swift but one of
those compromises in the time available. :-)
The application required the receiver to remain in operation
even when a nearby (physical closeness of separate antennas)
transmitter was operating on a different carrier frequency.

>Some calculations can be made of the expected performance. Assuming IF

>deteriorates the sensitivity my the same amount. Is this relevant
>depends on band noise level.

...OK, I'll take those numbers at face-value, too lazy to do the
plotting (and I ran out of quadrille paper). :-)

For other confused readers, again: The slope of the 3rd Order
input is steeper than the normal mix product slope, so the
offending input level would be higher than the desired level.

>The third order intermodulation question is very relevant when a large
>number of offending signals can produce intermodulation of m*f1+/-n*f2

>situation when a large number of strong signals are allowed to enter
>the mixer (e.g. one or more broadcast bands). Thus, it appears as if
>even +30 dBm IP3 is not sufficient if very wide input filters are
>used.

Whoa...the slope of 2*f1 +/- 2*f2 or 3*f1 +/- 1*f2 is steeper than
2*f1 +/- 1*f2...it is 4th Order, not 3rd, so the offending signal level
versus desired would be greater compared to a very low desired
signal level. It is easier to calculate LO second harmonic plus/minus
desired fundamental (or vice-versa) in terms of mix products and see
if they fall into the IF range. Zero-beat or near that are the ones that
can be heard.
Yes, I know that other harmonics in different mix Orders are
possible, but their occurrance becomes more rare as the Order is
increased...and the offending signal levels would be strong.
Decades ago I came across a very quick method of checking
for undesireable mixer products in Electronics magazine, taking
the lowest over the highest frequencies as a fraction less than 1.
Possible trouble from zero-beats would happen when harmonics
of each resulted in a fraction having both an integer numerator
and denominator; i.e., "1/2," "2/3," "3/5" and so on. The Order
would be, respectively, 3rd, 5th, 8th above. As the Order
increased, the mix product level would decrease.

>However, the question of an multi-multi contest station with multiple
>transmitters and antennas are on the same site is a bit different.

>There are only a very few, but very strong signals at the receiver
>input, but the likelihood of generating 3rd order interfering signals

>and can usually be avoided by coordination between the operators.
>Thus, the previous 3rd order analysis is not very relevant for this
>situation. However, 5th and higher order products can be strong enough
>to be above the noise floor.

Please avoid generalities there. :-) Antenna fields' levels fall rather rapidly beyond the near-field...and those depend on the transmitter levels going into the antenna.

What I've observed on very strong nearby signal levels is nearly always just plain overload on a receiver input that can act as another LO, giving a true desensitization. This can be acute with sharp-cutoff tube RF amplifiers, almost as if they had a DC bias applied with CW signals. That isn't any intercept point problem. That's just blocking...but it is fairly easy to determine approximate levels ahead of time. It's also easy to test.

>However, on such contest sites, transmitter oscillator phase noise
>directly and the reciprocal mixing of the transmitter carrier mixing
>with the phase noise of the receiver LO and the receiver blocking
>will cause the most problems.

I'll disagree with the "phase noise" inclusion above until proven otherwise by a reference and experiment.

Phase noise has a definite effect on QAM signals and BER values but such signals are hardly used in amateur communications. Phase noise can show up as incidental FM on VHF and above FM transmitters in ham bands but that is at a very LOW level compared to the modulation. Phase noise can be pronounced in some DDS designs or fractional-N synthesizers, particularly from aliasing, but that is an inherent to equipment thing and not what we are talking about.

>With only one signal on each band (as the contest rules usually only
>allow for a multi-multi contest station) the problems can reduced with
>high power bandpass filters (installed between the rig and the linear
>amplifier). Such filters were described a few years back in the QST
>and help to reduce both the transmitter phase noise to other bands and
>reduce strong carrier signals from other bands that could cause
>desensing or reciprocal mixing with the receiver local oscillator.

I'll bring up another little point to investigate: Linearity of finals. They've become commonplace in amateur transmitters for all modes but they aren't inherently "linear." There is always some distortion in any final amplifier (regardless of bias class) but that can be found by a 60 db dynamic range (minimum) spectrum analyzer with passive attenuation between analyzer and transmitter.

Additionally, nearly all RF signal generators can output +10 dbm,
even the Heathkits. :-) With a signal generator it's a fairly easy
thing to crank it around on all bands to see if a receiver is really
performing as advertised in selectivity and intermodulation.

In a multi-station contest setup, 1 KW = +60 dbm and a second
receiver ought to have at least 60 db of total attenuation from
that source to avoid going above 0 dbm input interference.

>In such situation, the IP3 level is not so relevant.

True. :-)

Thanks for the idea. About a decade ago I was chasing some 10-15th
order intermodulation products on a repeater input, which was located
in a tower with several broadcast and communication transmitters, the
calculation took quite a while in those days :-). Finally, the culprit
was some rusty bolts in a supporting structure. With high field
strengths, quite high order products can be created.

>to the modulation.

I think that you are confusing two things. A very bad phase noise
performance can cause incidental FM and bit errors even in a single
signal condition (only the transmitter and receiver on the band)
regardless of signal strength.

However, a strong external signal can act as a local oscillator and
mix with the phase noise sidebands of the actual local oscillator,
some of these reciprocal mixing products will fall into the IF
bandwidth increasing the effective noise floor. This affects all
modulations and requires strong offending signals.

This can be observed in congested antenna sites when notch duplexers
are used in repeaters. While the notch tuned to the own _transmitter_

frequency in the receiver line (connected to a common repeater antenna) will effectively block the own transmitter signal from the receiver, radiation from other antennas will get into the receiver with only minor attenuation. In many cases, the noise problems in the receiver can be reduced by replacing the receiver PLL with a clean crystal oscillator and a multiplier, thus reducing the reciprocal phase noise mixing products.

The repeater own transmitter line also requires a notch tuned to the repeater _receiving_ frequency to block any transmitter phase noises going from the transmitter to the common antenna and back to the receiver.

So there are really two separate problems with oscillator phase noise.

One with deviations comparable to the actual signal affecting the modulation constellation regardless of signal level (not relevant in this discussion).

The other is due to weak (60-120 dBc/Hz) below carrier noise sidebands which can spread out several megahertz from the carrier, but when the carrier is in the +10 dBm to +60 dBm range the sidebands can have considerable power (-130 dBm/Hz .. 0 dBm/Hz) above the thermal noise (-174 dBm/Hz), which can directly or trough reciprocal mixing cause all kind of reception problems.

>>With only one signal on each band (as the contest rules usually only

>attenuation between analyzer and transmitter.

The "linear" amplifiers will produce all kinds of intermodulation components from a multiple frequency base band signal (such as speech) and harmonics (filtered out by the transmitter LPF). However, it does not generate much phase noise of its own, only amplify existing input broadband phase noise and possibly create some low level reciprocal mixing between the signal and the input phase noise. Thus, a bandpass filter between the rig and the linear amplifier will reduce the amount of phase noise reaching the linear amplifier and also reduces the opportunities for reciprocal mixing in the linear amplifier.

>In a multi-station contest setup, 1 KW = +60 dbm and a second
>receiver ought to have at least 60 db of total attenuation from
>that source to avoid going above 0 dbm input interference.

Reaching a 60 dB isolation in a small space can be hard, unless two vertical antennas are stacked one above the other.

At MF and lower HF, the antenna near field extends to quite a few meters, so calculating the field strength can be problematic if you are in the near field.

The reverse voltage rating is on the order of 20-30 volts per section so
you can make an estimate of how many sections are in the series stack.

I did not see this when I got into RF design as an engineer in 1977. I didn't even see this when I was a technician in the early 1970's. Every indicator when I was young was that the electronics industry was nothing but up up up. All my fellow engineers graduated from US engineering schools. There were no off shore facility that you were dealing with. Your factory in your town was building your product for the local market. Don't blame male menopause on this. If you want to believe that there is some kind of future in electronics in the US, then by all means pursue this route. More and more of the US manufacturing centres are closing. A sizable number of electrical design centers are now not even in the US. Go out into this world and look for yourself. You won't find, if you're objective, a similarity at all with that of the past, in any decade. The Chinese electrical engineering design centres are expanding rapidly now and the ones in the US which used to be operated by companies like TI, Burr Brown, TRW, Motorola, Westrex, etc are going the way of the horse drawn buggy.

As far as the contracting route goes, why should I, as an employer, hire a contractor to do my rf design when I can use a Chinese design centre for the same or less money and, at a tax break, to do my work? They have all the latest analyzers, anechoic chambers, software and other tools that some guy working from his home doesn't have, no matter how expert he is. Even if I were the best and could get $200 per hour to contract, how can I afford a Cadence license to do capture, layout, simulation, and fabrication when these cost $15,000? Not only this, even if I have a Cadence service agreement, who is going to fix the normal problems encountered in the design environment on a timely basis? If I have one license and the Fortune 500 or Chinese company has 35, who gets first attention by the HelpDesk? Reality has to set in when addressing these "incidentals" especially when you're talking about going from the bottom of S band to the top and beyond. Go ahead! Try laying out a board for 5.8 GHz using PCB123 on your Wintel box and getting the Po to be 37 dbm with stability even into a 14 db return loss.

Bottom line: as much as it pains me, if I had it to do over again and was worried about this point in my career, I would have been a civil engineer engineer instead of electrical. Someone will always need a bridge or road constructed. I wouldn't even need to worry about the locality question. They are needed everywhere, even in the US.

Steve

If I had to do it all over again, I'd go into some economics-related field.
People tend to pay you well when you have your hands on their money. :)
I might spend 40 hours a week doing something less than lovable, but I'd
have 128 hours a week, and a whole buttload of money, to have fun with.

yes, they are "low" cost and have a "lean design"..so the buyer gets what
they pay for.

i've used the 10m FM rx kits. More than functional but the crystal was not
included.

FWIW, something I used to do that I picked up in an electronics research
dept I worked in back in the dark ages before lights were discovered, was
to take my wife's used stockings, etc, with a relatively fine denier, and put
on a frame made of 1X2 planed wood. For my work that would last years..

So then I would have a "sheet" of "silk" and I would write on it with soap.
After the soap dried, I would spray the silk with a filler paint, and after that
dried, I would wash out the soap.

This was okay for relatively crude work, but it can be fined down using
rubber stamps fo lettering, or laying out something on paper and putting
the sreen on it and tracing out the lines.

For real fine lines, I used a lettering pen (yes, with soap) and a rule laid
across the frame to hold me straight.

Again, FWIW.

And it was a long time ago.

Hi, Jim!

Having silk screen printed a variety of items back in my youth and college days, what did you want to know? Where to get the supplies? Which ones to use?

I've only done this on paper and card stock and using hand-cut Rubylith resist film, but photo techniques are easy nowadays. And PCs to create the original artwork are lots more capable than they were in '73 (!!).

Here in Santa Rosa, California, the local art supplies shop carries a wide range of the supplies (screen, frames, squeegees, ink, resists, books, etc.). I'm sure the Internet and mail order do so as well.

Let me know what you want to learn - perhaps I can help with the search.

Steve, since you brought up the situation, on an amateur
radio reflector you are getting a varied background bank
of answers with the common denominator of Ham Radio.

If I may inject the first rule of employment in the U.S.,
at least nowadays:
.....It's not what you know, but who you know!.....
Your degree paper/lamb's skin is scratch paper.

Now just think about it, if you want to build bridges then
get on it. Get back in college and take courses and make
some contacts. I think you will find that your OJT is way
more valuable than that academia degree which is usually
courses in ancient history when you get into the real world.
Oh yeah, ok.............guess what, bridge builders have a
need for EE's and RF savvy E's because even the old
spit in the dirt and make concrete profession has gone
hi-tech.

Hey, you will do just fine, at least you know the status
of the profession and want to better yourself.

GL in the contest.....73.....Walter, AG5P

I looked at the Macom web-site, they had some rf devices with the
prefix PH in the part number, beginning with PH0104, but nothing as
far back as those I am seeking data on.

Thanks for the lead Mike, I'll try some of the microwave designers
here in NZ and see what can be found.

Thanks for explaining more clearly than I did, Paul.

>This affects all
>modulations and requires strong offending signals.

And when the band is full of strong signals of various modulations,(as in a
contest) the apparent rise in the effective noise floor can be enough to drown
out weaker signals - without the receiver actually being "overloaded" by strong
off-frequency signals.

End result is that you can have a receiver that appears to be very sensitive in
the lab, when connected to a signal generator and dealing with just one signal.
But when said receiver is in a real-world environment of a band full of loud
signals, the usable sensitivity is degraded to the point that the weak ones
can't be heard. Meanwhile, another receiver whose phase noise characterisitics
are better but whose "lab" sensitivity is worse manages to hear those weak
signals.
>
>This can be observed in congested antenna sites when notch duplexers

In the HF case, the strong offending signals may be much closer to the desired signal in frequency, and so their level doesn't need to be so great in order to cause trouble.

The Ten Tec website

http://www.tentec.com

has a decent explanation of the subject with HF examples.

>
> 73, Fred, K4DII

The reverse voltage depends on the diode configuration. A each diode
in a 4 diode bridge sees no more reverse voltage than the capacitor
voltage (assuming no load current). Each diode in a 2 diode half
bridge used with a center tapped winding sees twice the capacitor
voltage. Allowance for surge voltages and high line should be added
to these factors.

I have a few of these - various models. Where can I get info on how to use them (other than sticking them in a Motorola radio)? Seems like pinout data is not readily available on the Internet.

For a full wave bridge configuration, 0.9 x the RMS voltage applied to the bridge is the output voltage before application to the filter cap, then you use 1.41 x the RMS output of the bridge = final peak voltage output of the filter cap.

Yes, they only have current models on their web site, but you can email them,
or give them a call. They are a pretty good bunch.

I had the (dead) battery pack in my radio. It was eight AA NiCad cells
in a cylindrical aluminum case, split in the middle for charging. I
replaced it with a plastic battery holder for eight AA cells, wired it
as originally, and just using regular rechargeable cells.

Good luck, Peter

Old common "d'Arsonval" meters with permanent magnets - if the magnets weaken the meter goes out of calibration, I suppose. Anybody know what to expect with old meters? A gradual lessening of sensitivity? How long - how much loss? Guesses?

I suppose it depends on the magnet material. I remember that for ceramic magnets, 1% of the initial strength fades in milliseconds; 1% in seconds, and the next 1% in about a million years. So I suspect that calibration change isn't much of an issue...

I puchased an expensive Eagle multimeter in the very late sixties (couldn't afford an AVO 8X) about the same size as the 8X.

By the mid 1990's it was reading 10% low even with the meter mechanical adjustment full on, this I put down to aging of the magnets. Regrettable I forcibly retired it to the bin whilst making room for new gear!

No one can predict accidental semiconductors (rusty hardware). :-)

My reference was "Linear Scales Show Mixer Harmonics," by
Roger T. Stevens, Sanders Associates, published in Electronics
magazine, January 10, 1964. Stevens' method was to make a
fraction of mix products with the numerator being lowest frequency
and denominator the highest frequency...or "low over high" fraction.
He did this separately for mixer sums and differences. The result
is then solvable for an exact zero-beat if either mixer input frequency
is unknown. Stevens' accompanying charts were two linear scales
marked with various mixing Orders. It was absurdly easy to use
compared to other methods which involved two-dimensional graphs.

PM and FM have the same sideband content, differing mainly in phase relations. There is a slight difference due to modulation frequency. I can go back to John Carson's original equations if you like (few others would care to see that...). :-)

Some mythology has been building since the first appearance of the PLL in "digital frequency control" a quarter century ago. The argument (false) is that they all have phase noise...because today's spec sheets give finished PLL and DDS components' phase noise. A well-designed and executed PLL will have predictable phase noise and that will be very close to the carrier. What few realize is that common crystal oscillators can also exhibit phase noise if they are not carefully designed. Overtone oscillators such as the Butler circuit are prone to this if not carefully tuned. If that is followed by a string of integer multiplier stages, the phase noise is also multiplied at the output.

Fractional-N and the rest of the DDS family are quite prone to alias frequency generation if not designed and executed properly. There are quite a number of application notes on the Internet covering that, all available for free download (Analog Devices and Philips, for example). Many hobbyists shy away from commercial SOC devices (systems on a chip) principally because they don't understand the method or the internal complexity or the (too often) needed serial data input for frequency control. Therefore, "digital devices are bad and have many faults." :-)

What is so curious (to me) on such mythology is that those making the statements are using one or another digital synthesizer in ready-built equipment...and not finding any fault with them. :-)

>However, a strong external signal can act as a local oscillator and
>mix with the phase noise sidebands of the actual local oscillator,
>some of these reciprocal mixing products will fall into the IF
>bandwidth increasing the effective noise floor. This affects all
>modulations and requires strong offending signals.

Quite true as a generality, but the fault is not always in the first mixer or the local oscillator of a superheterodyne. With very strong unwanted signals at the antenna, intermodulation can exist after the first mixer, before the ultimate selectivity component (usually a crystal filter). That's a matter of watching stage gains of the entire input half of a receiver at various RF gain levels. It also requires attention to the selectivity between the first mixer and the final IF filter.

Trying to listen to weak signals with very strong somewhat-nearby frequency stations lets you hear the higher modulation components of AM in the strong signal. Those can be below specification yet they can get through the input half selectivity in a receiver...and they can sound as if they are "noise." That "noise" isn't due to any LO phase noise of any kind.

>This can be observed in congested antenna sites when notch duplexers
>are used in repeaters. While the notch tuned to the own _transmitter_
>frequency in the receiver line (connected to a common repeater
>antenna) will effectively block the own transmitter signal from the

>with only minor attenuation. In many cases, the noise problems in the
>receiver can be reduced by replacing the receiver PLL with a clean
>crystal oscillator and a multiplier, thus reducing the reciprocal
>phase noise mixing products.

A rather long time ago I was responsible for nine 24-channel microwave radio relay terminals. A 1.8 GHz General Electric circa-1950 design, the transmitter (12 W peak) and receiver were on the same antenna, running full duplex. Tx and Rx were combined in a very fussy to tune double bandpass filter or diplexer. By picking separate Tx and Rx frequencies at greater than 5% of band center, the diplexer gave greater than 100 db separation of Tx and Rx. Crystal oscillators were 5th overtone types followed by multipliers, last in the chain a septupler (7x). That oscillator (not strictly a Butler type) could be falsely aligned to hop on and off the crystal overtone causing the equivalent of noise at the receiver video detector. When properly aligned it was okay, but we had to very carefully check tuning if the oscillator tube was replaced.

In the early 1970s I used some L-band sources that were PLLs using very short pulse sampling, the sample phase compared to a crystal oscillator phase. Those had excellent phase and frequency stability and no phase noise of sufficient quantity to affect low-level receiver signals. Note: Sampler systems can be very affected by amplitude noise of an L-C oscillator, as opposed to conventional limiting-clipping-to-baseline prescaler input digital circuits of PLLs.

>The repeater own transmitter line also requires a notch tuned to the
>repeater _receiving_ frequency to block any transmitter phase noises
>going from the transmitter to the common antenna and back to the
>receiver.

Diplexing systems aren't new. Proper diplexing design for full duplex operation is not simple but requires care to keep unwanted signal attenuation high. If the modulation is relatively broadband, then the higher-frequency modulation components extend as far on either side of the carrier whether AM, FM, or PM. If the un-wanted carrier is too close in frequency, then the sidebands are going to be less attenuated and their content stronger. They can appear as "noise" of some sort...but not necessarily as phase noise.

>So there are really two separate problems with oscillator phase noise.
>
>One with deviations comparable to the actual signal affecting the
>modulation constellation regardless of signal level (not relevant in
>this discussion).

I'm familiar and agree to keep constellation talk to a minimum. :-)

A good opthalmologist is always needed for 64-level QAM viewing.

>The other is due to weak (60-120 dBc/Hz) below carrier noise sidebands
>which can spread out several megahertz from the carrier, but when the

>considerable power (-130 dBm/Hz .. 0 dBm/Hz) above the thermal noise
>(-174 dBm/Hz), which can directly or trough reciprocal mixing cause
>all kind of reception problems.

OK, that's what I've been talking about...but I keep emphasizing that
it isn't always just phase noise. :-)

If it is actual phase noise and all stages after mixing are reasonably
linear or the level is low enough to keep away from distortion, then
the phase noise power just adds algebraically to natural noise power.
If induced noise level (of any kind) is strong enough to cause
intermods anywhere, the noise addition is no longer algebraically
additive.

In a multiple-pulse full-duplex RF situation, I've had to get elaborate
in an AGC-on-(front-end)-noise since non-time-synchronous transmit
pulses would put a "hole in the noise" due to severe limiting in the
receiver. That's an extreme example, of course.

>>I'll bring up another little point to investigate: Linearity of finals.

>mixing between the signal and the input phase noise. Thus, a bandpass
>filter between the rig and the linear amplifier will reduce the amount
>of phase noise reaching the linear amplifier and also reduces the
>opportunities for reciprocal mixing in the linear amplifier.

Ahem...a bandpass filter won't reduce any close-to-carrier phase
noise. Phase noise is strongest near the carrier, decreasing in level
on either side. Usually. :-)

Non-attention to higher speech components of some speakers, even
males, can result in limiting-clipping effects in a linear final amp.
That results in a wider sideband content and can be within the
passband of the filter...but it sounds like intermittent noise.

I'm assuming the DX island location has at least 50 meters of
distance between different antennas. :-)

To measure the crystal reference signal in your 3001?
I used an Optoelectronic's 3-GHz handheld counter.
The only other option is a spectrum analyzer where you
can accurately peak the preselector for max. signal
at 1440 MHz.

Pete

Steve,
Well, your story sounds a lot like mine. I started in Ham radio at 13 years old, went off to college to become an EE and worked as a technician while going to school.

I made one critical decision during that period of time that I will never regret, I took an internship the summer I was 19 yrs old. I got to talking to one of the Engineers at the company I was working at. He was in his mid 20's and he told me to be sure and do all the odd and exciting things I have ever thought of doing before I graduate. He spelled it out for me as "You will have the rest of your life to sit behind a desk, don't waste your college summers doing these internships."

I listened to his advice and never spent another summer in an office. The following summer I worked as a fisherman in Alaska. Being raised in Livingston, MT I had grown quite fond of the mountains, fishing, and forests. The summer I returned from Alaska, there was a forest fire in the moutains south of Livingston. It struck my curiosity and I decided to try working as a wildland fire fighter the next year. Seventy five job applications later (Electrical Engineering isn't exactly high marks on a fire fighting job application) I found my self near Seeley Lake, MT working as an Initial Attack engine crew member. When the summer and fire season was wrapping up and it was time to go back to college (in Bozeman) I discovered that for the very first time in my life I did not want to leave the job. I had made modest money compared to my technician jobs, but it was the most rewarding work I had ever done. I had met a girl (who 5 years later would become my wife). It was a great summer.

I continued to fight fires every summer. My last semester of college I refused to interview with any companies, I got into the best physical shape of my life and was the only student in my MSU EE graduating class to go off and work for $10/hr fighting wildland fires. It took me six years to complete my degree and here I was swinging a pulaski in the dirt, cutting down trees, and loving every minute of it. I had made it on to the Bitterroot Hotshots and was living the good life. I kept that up for two more years, working fires in the summer and being an engineer/technician at a small engineering company in the winter.

Well the winter of 2001 rolled around and I was not able to get my job back at the small company I had previously worked at. I started knocking on the doors of larger ones. Sure enough I landed a job at a larger company in Bozeman. They made me an offer as a year round EE that I couldn't refuse. I decided to give up fire. Winter turned into Spring, Spring into summer. The temperature rose, the air got dry, and the lightning started to pop. Smoke columns were everywhere in sight as I would drive home from my desk

job. It was driving me insane. I had a good job (by most people's standards) but I would get depressed thinking about being there, designing stuff for other people till I retired. Then like a saving grace to me the stock market crash finally hit the company I was working at. I was layed off in July of 2001. To my amazement, I was completely thrilled. I called the Forest Service and two hours later I was filling out my hiring papers to work on the local fire crew, back in my element.

I continued with fire and am now a USFS Fire Crew Leader by occupation. My winter will be spent working as a radio technician for the Forest Service. My engineering education has by no means been a waste, my basement is completely filled with test equipment, homemade PCB's and hundreds of projects I have spent doing in my free time, some work, some don't, but all have been fun. The challenge that originally intrigued me about engineering has become exciting again. For me, the key was doing a job that I love to do as my occupation and using my education for my own gain. Who knows maybe somewhere in this pile of homebrewed half complete projects, there is a design that will allow me to retire on something besides a fireman's salary. The advice I would give you is chase after that dream whether it's fighting a fire, flying a fighter jet, or driving a truck. Throw caution to the wind, just be willing to adjust your lifestyle to fit your new occupation. Beleive me, it may take some time, but before long the ol' soldering iron will come out again, this time for no one's challenge but your own. It makes all the difference in the world.

I really don't think the magnet will change perceptably in our
lifetimes and the spring won't either, unless it can, and does, rust.

I agree with the other poster who mentioned the series resistors.
These are MUCH more likely to change, plus they always change upwards,
which would make the meters seem to have lost sensitivity.

Of course, that's not the only thing that might change to change the
calibration. It also depends on the spring constant of the restoring
springs.

In practice, I haven't noticed it to be a problem, but I could check
some 50-year-old meter movements to see how they've held up, assuming
they were calibrated correctly to begin with. Think it's worth
spending a few minutes on? (These days, anything I need to know
accurately, I measure digitally...mechanical meters have a place, but
for me, it's generally getting quick relative indications or seeing
trends; much easier to find a minimum or maximum with a mechanical
meter than a digital one. But even easier with a tone whose frequency
is proportional to the measured value!)

Cheers,
Tom

I am in search of long telescopic whip antenna elements for a portable loaded HF dipole I am making. The largest I have found thus far are 72"

extended, and I need 96-108", about .25" diameter, not more than .50" fattest section, with a threaded or punched base for mounting. I have tried Rat Shack and the usual catalog suppliers (Mouser, Fair Radio, Ocean State, AES) without success. Does anyone know of a mail-order source for such parts?

>Jerry W4UK

Unless the meter has been physically or magnetically abused,
they should last a human lifetime...at least to within their best
calibration percentage. Note: "Magnetic abuse" refers to a
VERY strong AC field.

Every d'Arsonval meter is actually a very small power meter. It
has an internal resistance and develops a voltage drop across
the (nearly always copper) meter motor coil. That drop is
typically 50 mV full-scale but can vary depending on make and
model and full-scale range.

Most run-of-the-mill d'Arsonval meters are +/-2% to +/-3%
accuracy over a stated temperature range. The internal copper
resistance causes the most change in accuracy over temperature.
If greater accuracy is required, a mirror scale (extra cost) is
needed to reduce reading parallax to a minimum and some
high-accuracy models have some temperature compensation
of the motor winding built-in. On common panel meters,
expect a normal 2% scale change from brass monkey cool
temps to sweltering hot T-shirt temps. All due to copper meter
motor winding and external series or shunt resistors.

Yes, the internal magnetic field can change in time but that is
such a small change that you need a very fancy calibration lab
to detect it along with some very costly reference standards to
use for comparison.

For a stable current or voltage measurement need, a packaged
op-amp with band-gap voltage reference and selected precision
resistors reading out to a digital display is going to cost less and
be more accurate over temperature than any d'Arsonval meter.

Possibly, having bought it for home use, I preferred it to the 8X
which I used professionally. However with cheap Digitalmm's it fell
into disuse and when I resurrected it for a specific task it had lost
equal sensitivity on all ranges. I did open it up and have a quick
tweak but the aluminium sclae plate had also begun to turn to powder
so it was binned. Shame on reflection, but that's nostalga for you.

I have several 40+ year old Simpson panel meters, which all test to full range with as little as 25mV. The tolerance of the shunt used in the circuit and any calibration pot are where most all of the error will be found in these circuits. To assure that your meter will hold it's cal. for the foreseeable future, use only 1% resistors for shunts, and 1% cal pots, which will give you an overall cal tolerance of + or - 4%. If you need better that this, you should be using a digital meter.

But don't make the mistake of thinking that just because a digital meter shows you lots of numbers past the decimal point, that it's any more accurate than your old Simpson. Read the specs carefully -- and unless it comes from a reputable manufacturer, take them with a large grain of salt. Digital meters have resistors too.

But it is true that a properly designed and calibrated (and probably expensive) digital meter can be made to be more accurate, and readable to greater resolution, than the best analog meters.

I've not seen any change in meters that haven't been abused or the seal broken. Why don't you establish a full scale current with a good battery and good pot with a known good digital meter. Then check your meter for full scale deflection by putting it in series, you will have to turn down the pot because the inserttion of your meter will add some resistance. There's a pretty good write up in older ARRL handbooks on determining the meter movements specs. Let us know what you find, and good luck.

Here is at least one more... S/N 2600. Have all options but the audio filter/clock and the 100 wt PA. Works great! Just before the context last weekend, managed to pick up (from Virginia) Chatham and South Cook islands using 5 watts and 60 meter long wire on 17M SSB.

Modified mine for PSK31 addind PTT I/O & isolated audio I/O (see my web page) with DIN recept. on the rear.

The kit is well engineered and went together easily, but with my luck, had two unusual problems which had me pulling out my hair for a while. One of the T/R control line runs (8T) had a Cu whisker (~ 0.0005") under the conformal coating, shorting it to the output of an opamp. ...A 30 second fix AFTER I found it! Also the MCU (U6?) analog input pin for power control had an internal short causing the TX to go full power all the time. After Elecraft sent me a new MCU, all worked fine.

Kevin,

I liked your story a lot. It was very interesting and somewhat uplifting. It still sounds like you have lots of time left in your life. Unfortunately, my odometer has gone around a couple of times and can't do anything physical to speak of. I'm still looking for something that I can do and be as constructive as possible in the process. I'm good at explaining science and electronics and am looking of a way of doing that without going into the public school system where your teaching has to conform to the PC requirements of the day. Good luck in the fire fighting.

BTW, I fought fires in the Navy, but I was 18 and only did Class B and C fires.

:-)

Steve

Do they have solid pins or do they have pins that look like stranded
wire? Send me an email or do another post and I'll get you the info.
BTW, you'll need a 7.5 vdc supply to power them, no matter what. As I
recall, they don't draw more than about 2 mA even for the UHF ones.

Any. When you're 23 and your company sells out you think its an
improvement. When you're 50 and have gone thru a whole series of
consolidations and still have a job, you consider yourself fortunate.
You mention teaching...one of the most admirable of professions for
those who care about their industry and the newcomers. Not as lucrative
as contracting but...you have experience and that can be the best
teacher and very rewarding personally... and it may come very easily for
you.
Just do it. People with skills don't starve to death because they made
a bad choice.

-Bill

The question of meter sensitivity to temp changes came up in a
different area recently and I was surprised when someone claimed to
have found a rather large temp dependence in a d'Arsonval meter meant
for automotive use, a VDO tachometer.

How is temp compensation done on such meters, and is it possible for
cheap meters to have much more temp dependence than even a well made
but uncompensated movement?

thanks,

-

It would be interesting to put capacitance across your resistors
to tune out the inductance. See if you can bring your swr down
closer to 1.

This might be acceptable when using the dummy load for a specific (narrow) frequency band ,but not as a universal (multi band) dummy load. Strictly speaking ,it would only be suitable for 1 frequency for which the load would be strictly resistive.

Not sure why a dummy load is needed, hi. Just do the testing with an antenna, any evening, on top of the foreign broadcast stations on 40 meters. Another alternative for daytime work is to make a dummy load out of inductive or non-inductive resistors, use an "antenna tuner" and you've got your 1:1 load.

Hey guys, the things aren't linear in the first place. As I recall they are calibrated and read most accurately at their midscale. Any change could be reversed by recalibration.

Dick

Source record: 40275

Typical calibration is done at FULL SCALE reading, because the maximum error will happen at that point too. So, you calibrate there to minimize the error.
The mid-scale error will be neglegible. For example: My plate current meter on my HB HF amp has a error of + or - 10mA @ 1000mA. full scale reading. My grid-current meter has an error of + or - 1mA @ 100mA full-scale reading. The typical meter will not chenage much due to temperature, provided the meter movement is enclosed. Tempature will affect the shumt resistor value & the cal pot, for a small amount, but this should not be a factor when the unit is inside a house where the temp is fairly consant. Units that are outside inn the weather need a heater inside to maintain a more or less constant temp. Cold lowers the resistence, heat raises it.
But, all meters are relative anyway.

3516. Pattern of *Tri-Di-Pole*+++

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-11-02 17:19:30 UTC
From: wa8mea@hotmail.com
Message-ID: <8a260fb2.0211020919.1d04a7f@posting.google.com>
Source record: 40279
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur,rec.radio.amateur.homebrew,rec.radio.amateur.dx

Could use some help from some of our more technically minded antenna buffs.

Several years back, I came up with a general use dipole for SWL's that I named the "Tri-Di-Pole". The "Tri" meant a third wire element connected to the ground side of the dipole at the appex, with this wire running straight done to be connected to a ground rod. This was invented more for practicality purposes, so SWL's didn't have to fiddle with ground wires soldered to those tiny little external antenna phone plugs that are in common use for most portable shortwave radios.

But over the years, several hams have called me about using this same antenna for transmitting. To be honest, I've never tried it for transmit. I just don't have the real estate to experiment with it. But now I'm curious, how well would it work for transmitting purposes?

My devices are born more out of a practical design than technical. I freely admit I'm not all that antenna theory book smart. My questions: What kind of a pattern would this antenna have? Would the take off angle make it highly suitable for DX on certain freq bands? And what would I have to trim? Just the two standard dipole elements? Or would I also have to trim the third ground element? Anybody ever try such a design for transmit and on what freqs?

Thanks for any/all input.

Hello,

PC 900 is a B7G base triode with a heater of 3.9V 0.3A, Va is 135V
Vg -1V Ia=11mA Wa 2.2W Ik=20mA max, u=76 and the gm is 14.5mA/V
A very promising valve to experiment with in low-level stages, both
audio and HF/VHF amplification. It was developed for use in VHF and
UHF television tuners. The low heater voltage makes it very easy to
use in an ordinary 6.3V heater system, just use a dropper resistor of
8.2 ohm 2W and you are very close to 3.9V

I have 400 pcs in stock and I will sell them at only $ 5.00 each or
$ 2.50 each if you buy 100 pcs or more. The valves are NOS, in mint
condition, original boxes and the label is Haltron, but they are
rebranded, and probably made by Philips or Siemens.
Have a look at my website www.demostenes.no and e-mail me if
interested.

Best regards,

I'm about to put together an antenna switch for my shack and I had a few questions and I figured the NG could give me a little push in the right direction.

Much like a dummy load an antenna switch is very simple. But it is there anything special I should take into consideration? My needs are simple. I need an output for my Omni, an output for a beam, Output for dummy load, and a spare output for experimental/temporary Antennas. Simple right? Grab a project box, some spare SO-239 Connectors and a 4 position rotary switch...right? Is there any reason why I cant just switch the center conductor of the feeds and then the outer shields are all grounded together right? Am I making sense? I would like any unconnected antennas to be grounded (outer shield to center pin) and a position that grounds all outputs when my station is off line. But I'm not sure how to do this yet. I've been thinking it over, but no good ideas have come to mind. I'd like something simple and elegant that keeps the number of components to the absolute minimum. With a few switches I know I can do it but I was hoping there was a way to keep the switches to a minimum and different settings down to the absolute minimum.

I'd also like to be able to plug both my radios into the antenna switch. I guess the idea is I'd like to monitor two different freq with two radios on one antenna. But I think when transmitting with one rig is where I would have a problem. How could I go about simply and effectively separating the rigs during transmission? A radio with a dual band monitoring function is just not feasible at this point and really doesn't interest me. I'd like to use the equipment I own now to effectively monitor the freqs I use.

If it makes any difference in construction technique or components I operate on 11 meters and am only broadcasting 4W. I appreciate any suggestions or links to give me an idea of my next step. I'm heading out this afternoon to pick up a few parts for other projects and figured if I need something I haven't considered now is the time to ask. Course the more trips to the parts house the better. I love wandering the aisles, something all ways jumps off the shelf and screams "BUY ME! You need me. Just think what you can build with me!"

Thank you for any ideas,

Dave

3520. Works great on the second go round (was: How can you screw up a Dummy Load?)

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-11-02 19:53:17 UTC
From: Dave <local_42@hotmail.com>
Message-ID: <N2Ww9.217366$qM2.71897@sccrnsc02>
Source record: 40282

Problem was in my construction technique. I did a pretty sloppy job on the first one. Built a second unit and paid attention to detail. Dummy load reads as close to 1/1 as I can see on an analogue meter. With the 2W resistors it can easily take 10 times what I'm pumping into it. Doesn't even get warm. I was all smiles Wednesday night when I showed my girlfriend the completed project (looks very professional, I think, inside and out) Of course she wasn't to impressed and I was a little mumbly when she said "Ok, looks nice, but what does it do and why did you build it" The logical answer of "It's a simple introduction to construction and useful for off air tune ups" did nothing for her. Oh well, I'm much the same when she talks about her horses, he he.

Thanks for all the input,

Dave

| Hello,
|
| PC 900 is a B7G base triode with a heater of 3.9V 0.3A, Va is 135V
| Vg -1V Ia=11mA Wa 2.2W Ik=20mA max, u=76 and the gm is 14.5mA/V
| A very promising valve to experiment with in low-level stages, both
| audio and HF/VHF amplification. It was developed for use in VHF and
| UHF television tuners. The low heater voltage makes it very easy to
| use in an ordinary 6.3V heater system, just use a dropper resistor of
| 8.2 ohm 2W and you are very close to 3.9V
|
| I have 400 pcs in stock and I will sell them at only $ 5.00 each or
| $ 2.50 each if you buy 100 pcs or more. The valves are NOS, in mint
| condition, original boxes and the label is Haltron, but they are
| rebranded, and probably made by Philips or Siemens.
| Have a look at my website www.demostenes.no and e-mail me if
| interested.
|
| Best regards,
|
| Arnold Goks&#65533;yr
|
| DEMOSTENES - N6899 Balestrand, Norway
| Tlf. +47 5769 1340 Fax +47 5769 1267
| http://www.demostenes.no
|
| Thousands of different valves in stock as well as
| sockets,transformers,books,caps,resistors and
| other components. Web site is updated every week.

| You can order on-line.
|

Short answer is that you can't transmit with that scheme. You can rig
up all the switches you need to make a 'matrix' of different
rigs/antennas, though.
Now if you really wanted to xmt with a scheme like that, what you would
want is some sort of RF activated relay or switch but I don't know if
that would even be fast enough to protect the 'other' set. Manually
switching it off line seems to be the simplest.

As for parts, a decent 'old' quality rotary switch, even the phenolic
wafer types, are generally adequate at that power level and frequency.
Ceramic would be better but not essential.

Good luck and congrats on the dummy load.

The old panel meters varied from the fantastic vane type to the lousy ones
of different varieties. They are nothing more than psuedo-static motors
and have mechanical as well as magnetic theories in play to make them
work. All these things vary with no predictability. The best thing to
happen in the last few years to decades is the advent of A/D's and digital
readout becoming practical. I started in elecctronics in the days of
graphical methods of solution, vacuum tubes, and panel meters and all I
can say is that now I threw my old analog meter in the closet and have a
more accurate and easier to use instrument to do my measurements than I
ever thought possible. This is especially true for resistance
measurements.

Question on cal? If it's off at mid scale it's off everywhere with
digital. Now I expect a flame from someone at ....uk telling me
otherwise, but I don't care. :-)

The method you propose is probably ok if you use a metal box and keep the wires as short as possible. The reason for the short wires is that when you separate the center conductor from the shield, you still have a transmission line, but one having a much higher impedance. If this section of high impedance line is too long, it'll affect your impedance match. This would probably be a problem only if it's bad enough to make your transmitter's output drop, but it's something you should strive to minimize. A better approach from this standpoint is to use a two-wafer switch and switch both conductors at the same time, making the connection from the connectors to the switch with small diameter coax like RG-58 or RG-174 (smaller). But it's a lot of extra trouble, is susceptible to problems like melting the coax insulation when soldering, and really unnecessary for what you're doing as long as you can keep the wires short. The metal box is important for two reasons. One is that the wires to the switch will pick up nearby noise on receive, and will radiate on transmit, and a metal box provides shielding. The other reason is that it'll provide a low impedance path between the antenna and rig coax shields, and by being the outer conductor of the "transmission lines" inside the box, it'll lower the impedances of these lines a bit. So get a metal box, but not one that's a lot bigger than you need, use the single wire approach, and you'll be ok.

Sorry, I don't know of a simple way to do the grounding thing with a common type of rotary switch. Maybe someone else knows a way. The

configuration is simple using relays (an SPDT or DPDT switch for each antenna), but that's considerably more complicated and expensive than what you propose.

For receiving, you might be able to get by with just connecting two radios to one antenna -- it won't hurt anything anyway. A generally better way is to use a "splitter". There are at least a couple of ways of making these, and you might be able to find one you can buy. This isolates the two receivers from each other but connects each to the antenna. A splitter also works as a combiner for transmitting, provided it's built to take the power. The down side is that you'll always eat 3 dB in a splitter/combiner. That probably won't be a problem on receive (although it could be), but it'll reduce the signal you're transmitting. Directly connecting receivers won't reduce this loss -- the only solution is a mechanical switch to select the radio you want to use for transmitting at a given time.

Watch out. Keep up that attitude, and you're likely to end up in amateur radio!

I don't have a good answer to that question. :-)

When I was specifying and buying instrument meters, I didn't much
care about what the manufacturer put inside the case as long as it
met spec and we could make a profit with it. <shrug>

In the course of that work, I did run into a peculiar temperature
problem with a previously-proven 1% meter circuit...2% error
between cooler temps of the final test area versus the engineering
lab! After carefully dismantling one instrument's meter circuit and
testing every component carefully, nothing out of tolerance was
found. The trouble lay in the meter range switch, a rotary of several
decks that also mounted the range resistors between decks. The
production foreman had used several "very straight" well-tinned
leads traded with a buddy at a capacitor manufacturer...they made
the wire cross-over connections between range switch decks look
nice. Those leads turned out to have a high nickel content and the
thermocouple effect of dissimilar metals produced the extra error.
We had to electrically compare a pre-production prototype wafer
switch assembly with a production model assembly to zero in on
the error agent.

Any dissimilar metal junction in a few-millivolt meter circuit can
cause problems over temperature. Errors don't have to be due to
the meter alone.

To "qualify" a meter of your own, just make a setup to compare it to some standard such as voltmeter circuit with a known resistor, the series across a stable supply measured with a 4 1/2 digit DVM (for accuracy). Take the meter by itself and soak it in a refrigerator (not the freezer) alongside a food temp gauge for a couple or three hours. Take it out and connect it, read the indication and note it. Let it warm up on the bench for another 2-3 hours, along with the food temp gauge, and measure it at room temperature...whatever the food temp gauge indicated. Food temperature gauges come in all sorts of ranges and are cheap, accurate enough to yield a reasonably good temperature value.

What you actually DO with the information depends on your final task. That simple test will yield DATA where no data was available before. Such data is better than a lot of talk back and forth based on no quantitative testing.

Only problem is that you may wish to have 50 or 75 ohm feeder
resistance, this may usually be accomplished with a 1/100 loop area
ratio,
so one turn out of 25 or 30turns doesn't give a useful connection,
it is probably 1000 ohm and you still need an amplifier to feed the
cable - I don't see it is practical.

A 50ohm output may need an amplifier, dependent on type of receiver
you use, some transceivers are quite deaf on LF/MF

I have a couple of B&W coaxial switches and they have a setup whereby the unused antennas are grounded. It's done by the shape of the moving contact of the switch.

You can't do this yourself. You could buy one of these switches; mine has 6 positions.

An alternative would be to do the switching with relays, where making any sort of relay logic is relatively simple. For these frequencies, you don't have to worry too much about lead dress as long as the size of the box is small, say less than maybe 6" in any direction. After all, a tenth wave at 11 meters is a bit over three feet, and you won't have a problem with a small box.

The main thing is, don't hot switch. That is, don't change switch positions while transmitting. You can damage the switch (or relay) contacts and/or the output stage of the transmitter.

in principle, yes, but it might work on a higher frequency band - say
2m, and provided the capacitance is small it wouldn't harm on HF

==========
Many years ago in the 1970s Heathkit supplied a kit of a 4 position single deck shorting switch with 4pcs SO239 socket which were directly soldered (no wiring) to the switch contacts . The sockets were positioned in a hexagon .There also was an external screw type earth connection . I still use the switch.

Some time ago I made for a club a remotely operated 6 position antenna switch with 6pcs 12V DPDT miniature relays with plastic caps which were closely positioned on a piece of circuit board leaving a slot in the circuit board through which the relay solder tags protruded . These could in this way be connected with very short wires and practically directly to 7 SO-239 sockets (to accept PL259 connectors). The SO 239 sockets were fitted (in line) in the lid of a die-cast aluminium box.

Each relay had its 2 changeover contacts put in parallel .

The remote control box had 6 LEDs in a panel with room for (antenna) labels and a multi-deck rotary switch configured such that with 1 relay energised the relevant socket was connected with a socket to be connected to the transceiver , while most other sockets were connected to ground

However 1 particular SO239 connector relay was operated the other way around ,it connected the connector with the transceiver connector when de-energised . This particular connector was for the dummy load.
Hence when the power to the relay box would fail ,the transceiver would always be automatically connected to the dummy load (fail safe principle)
When the dummy load would be selected with the multi-position switch , the relevant relay would be de-energised , but the respective LED would be 'on' .

I recommended that the unit should not be used for RF power in excess of 100 Watts (based on gut-feeling).
However during a contest the unit was used in the output of a 400 W Power amp. , be it without 'hot switching'
Upon inspecting the tiny relay contacts after the event I was very surprised that they still were in a prestine condition.

How was the meter calibrated? For VSWR it's forward power plus reflected,
divided by forward (as I recall...I've been known to miss a digit here and
there)

Not on a 10MHz scope you won't.
The bandwidth of the scope must be equal to or more that the freq your testing.
When you get the correct scope, you can place a piece of wire in the probe port and wrap a few turns around the coax. Read your output on a meter first, then note the level of the output on the scope screen, now you can use it to see what your PEP is.
If you get real fancy, you can use a RF sampling unit, that goes in-line with the coax,, and sends a sample of the RF to the scope port, which you must adjust the scope for a slightly less than full screen display, and adjust the sweep speed to a rate that you can see.

I'm looking for some 2.4 gig equipment to try both EME, ATV, and digital.

I've not worked on the 2.4 gig band before, so I know very little about it. The ARRL handbook does little more than aknowledge it exists. With all the shairing, it's difficult to find what frequencys I can use and what power.

I'm also looking for just plain information, or scematics. Something to build, buy, or modify for RX, and TX.

So far the highest I've been has been the 23 CM band.

I think we're limited to 50 watts out plus antenna gain, but I haven't been able to find much in the way of information on the band.

You could build a mixer to convert 50 MHz and 144 MHz signals down to 10
MHz. The Handbook has a suitable circuit for this.

For regulations, see the FCC rule book. I think the ARRL website even has them on line. For equipment, you might take a look at http://www.downeastmicrowave.com/ to see what they have available. ARRL also published a couple microwave books.

In ARRL Handbook 1995 , page 26.28 a mixer for HF sigs is described
utilising a SRA-1 mixer.
I have a SBL-1 mixer and a stable signal gen up to 184 MHz to be used as LO.
Would the SBL-1 mixer be capable of handling up to 144 -148 MHz using a
0-10 MHz oscilloscope ?

I think this is the timing source for a CDMA site. It uses GPS to discipline a xtal oven and they claim Stratum 1 capability which is the highest Bell standard for timing. I'd guess it's somewhere between a rubidium and cesium. I'd venture to guess the winner of the contest will have a frequency standard that is most nearly in phase with one the ARRL is using.

This device seems to me to "get" it's timing from the CDMA site. I wouldn't go
so far as to call it a "Stratum One" but that is just my opinion.

Assuming most frequency measurement will be with a very accurate counter, the
main
problem will be determining the frequency of the signal in the face of
constantly varying
phase due to fading. The advantage will go to those within "ground wave"
distance
of the transmitter.

Just my opinion

3545. need a spark gap transmitter for experiment

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-11-03 18:04:28 UTC
From: tagangchiou@yahoo.com.tw
Message-ID: <6a3d2a74.0211031004.3a9f9fc0@posting.google.com>
Source record: 40208

I would like to buy a simple spark gap transmitter for a scientific project. I wonder if there is one that I can purchase? I am willing to pay for building it.

The requirement:
1. have a spark gap (and standard components like transformer, L, C, and probably an antenna. If possible, I want a small loop antenna for experiment)
2. simple (so that I can measure different characteristics by replacing the L and C).
3. basic safety (e.g. at least with a safety fuse).
4. portable (I need to carry it to other places for measurement.)
5. not very fragile (It will be shipped to Taiwan.)
6. can transmit longer than six feet.
If possible, I want to operate it under low power so that it will not interfere neighbors' utilities. (If necessary, I will operate in a Farady Cage to avoid violating FCC regulations.)

Does anyone know where to order it, or is willing to help make one for pay? Thank you very much!!

Ps. Please contact me at <dc at media . mit . edu> (convert at to @, and connect the others). Please do not contact me at tagangchoiu at yahoo.com.tw because it receives too many spam mail. Thanks.

Best regards,
David

You can attempt to account for the propagation error by monitoring the standard time signal stations closest to the ARRL FMT transmission frequencies, i.e. CHU at 3.33 and 7.335 and WWV at 15 MHz and tracking the error over time at approximately the same time the test will be conducted. If the radio you use accepts an external reference (the HP Z3801A for example) and you offset your BFO (also locked) to a known value you can then measure the frequency of the audio signal then use the radio's displayed frequency, the average of audio counts recorded during the test and the correction factor already noted to determine the received signal's frequency. At least that all sounds good in theory---we're going to use this methodololgy during the FMT and see what happens.

Thanks, but they dont run near enough power...I'm looking at running about
50 watts, or what ever is max legal limit right at the feed horn.
Besides, with all the X-10 pop ups, I swore I'd never purchase any of their
equipment.

Sounds like a pretty good arrangement to me.

My only comment would be to try and average as many measurements as possible.

Maybe on the next test I will set up and see what I can do.

Well, my counter offers only three time base intervals 0.1/1/10 seconds...the ARRL test signals will last 20 seconds at a pop and I'm going to use the 10 sec gate time...hopefully I'll get two readings per key down period, but most likely only one. For those with gate times down in the 3-5 second range the task will be much easier and as Bill suggests will provide more samples (no, we won't go down the road with statistics since figures always lie and liars always figure!). The old FMT as I recall had 5 minutes of key down on each frequency consecutively whereas here it's going to be 5 minutes simultaneously on all the freqs, so if your'e going to try to measure multiple test signals the mechanics of how you do all the switching is going to play a big role. My goal is to get two frequencies solid and if the S/N ratios are good and Murphy doesn't visit the shack I'll try for three of the four.

Good luck to those participating!

Reg,

Only problem is that you may wish to have 50 or 75 ohm feeder
resistance, this may usually be accomplished with a 1/100 loop area
ratio,
so one turn out of 25 or 30turns doesn't give a useful connection,
it is probably 1000 ohm, and you still need an amplifier or
transformer to feed the coax-cable - I don't see it is practical.

Tried the approach today, with coupling loop =1/100 of tuned loop
area, my loop on 136kHz has 26 turns in 1x1m square (Q=150, Cp=550pF),
and the coupling loop has single turn 50x50cm. It seem to work
satisfactorily, but I haven't measured the actual impedance.

Noise is peaked significantly when tuned, bakground noise increases
considerably when antenna is connected to the receiver. It seem not
necessary to use an RF amplifier ahead of the receiver converter
(74HC4066 mixer)

Should be OK, the SBL-1 goes up to at least 500 MHz. The SRA-1 can take more
input signal than the SBL-1.

3554. Re: RJELOOP3 was "Calculating self-capacitance of an inductor?"

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-11-03 23:34:41 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <aq4bqgjur1@venus.btinternet.com>
Source record: 40217

Dear Jan Martin,

We have a VLF receiving loop with 25 or 30 turns and a small value of tuning capacitor. It is the difficulty of obtaining a 10,000 pF variable capacitor which has got us into this awkward position. Inevitably the very high L/C ratio results in a high output impedance even with only one coupling loop turn.

I was aware of this when I wrote the program but was reluctant to change to another method of coupling the main loop to an ordinary receiver because it upsets the balance of the loop to ground.

From the point of view of receiving efficiency I would have preferred to use a single turn loop, as in a magloop, with a very big tune capacitor.

Even if the coupling loop has only one turn the antenna impedance seen by the receiver is of the order of 1000 ohms.

Your problem : You are trying to match the 1000-ohm antenna impedance to a standard 50-ohm receiver. Unfortunately there is no low loss answer. The coupling between 25 or 30 turns on the main loop and a tiny, single-turn, 50-ohm coupling loop is itself very efficient. Loop Q is an order of magnitude less than a copper pipe magloop..

As you say, if signals are lost in receiver noise then a preamplifier is needed. The preamplier can consist of a single bi-polar emitter follower which will have a high input impedance of the same order as the antenna. At VLF a small power transistor running at a few milliamps will have an output impedance around 50 ohms to match the input impedance of the main receiver.

I've forgotten the design formula for a simple emitter-follower impedance-matching anplifier stage. It depends on DC collector current. But if you want a really high input impedance then use a small power FET source follower. Come to think about it - the FET would improve loop Q. So go for that !

Use any two-wire, low-capacitance line to connect coupling loop to pre-amp.

This should help you get further forward.

Regards, Reg, G4FGQ

Were I in your position, I would consider a different kind of
transmitter, one that does not have the capability to cause severe
interference with things like public safety and government radio
services. How would you feel if your experiment knocked out, say, local
police communication, and someone got hurt or killed as a result because
help did not get the word in time to reach them?

> Farady Cage to avoid violating FCC regulations.)

It will indeed be necessary if you insist on a spark-gap type. I'd
be surprised if you find someone willing to aid you with something like
that.

Holy cow, are you not aware that at any time there are perhaps 100 million spark gap transmitters on the air in the USA. They are internal combustion engine spark plugs and they generally do not cause the severe amount of interference to vital police and medical interference you refer.

As for the orginal request, an automobile ignition coil, from the local junk yard, or Auto Zone will work fine for about an 1/8" spark using 12 volts. Insert a resistor if it produces "severe interference" Email if you need more details, but the interference is easily contained.

I suggest not doing this experiment because most everything about low power spark transmitters was discovered about 100 years ago. As for dirty things and severe interference, if the power is low, and not much of an antenna, you will be lucky if you get past the edge of your yard. I know, I tried it 35 years ago. Automobile spark plugs are low power spark transmitters. I can sometime pick them up at 6'.

Of course I know this. When someone says "spark gap transmitter,"
it makes me think of the 'real thing,' as in what they used during the
earliest days of radio. Perhaps I assumed too much from the original
post, but it sounded to me like this fellow wanted to build a full-blown
full-power spark transmitter.

If this is not accurate, then I can say I sit corrected.

3560. Detect direction of radio transmitter??

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-11-04 01:48:39 UTC
From: holysmokes99@hotmail.com

I am a total newbie to anything to do with electronics, radio waves, etc, but was just wondering something. If I placed some kind of radio receiver at the end of a narrow tube that was shielded againsst radio waves except at the other end (the opening), and had a radio transmitting source a few hundred feet away, would I be able to determine the direction of the source of the radio waves by turning the 360 degrees in all directions, with the direction of the strongest reception being the direction of the source?

I have really no idea the nature of radio wave bouncing, etc. Just curious....

Thanks,
Marcus

The output impedance of an emitter follower, in ohms, is about 26/Ie(mA) where Ie(ma) is the emitter current in mA. The output impedance of a FET source follower is about 1/gm, typically around 500 ohms.

This is very similar to trying to determine the direction of a source of sound by listening through a long thin tube (smaller diameter than the wavelength of the sound). There is a bit of directionality, but just as sound will refract around a corner, so will radio waves. Really good directionality only happens if the tube is large in diameter compared to the wavelength, as it is when you look through a tube (light is just very short wavelength radio waves). So, for something like 27 mHZ citizen band, you would begin to get good directionality if the tube were a hundred feet in diameter and ten thousand feet long. There are easier ways. Look up the yagi-uda beam antenna.

For example:

Actually, there are a number of things about how spark transmitter really worked that were apparently unknown at the time. Jack Belrose, VE2CV, has done a lot of research on and modeling of spark transmitters, and has built several. See for example http://www.kwarc.on.ca/hammond/spark.html. A Google search of belrose + spark will bring you several pages of references.

You do have a lot to learn. The short answer is no, unless you're listening for extremely high frequency signals (say, 10 GHz or so), where the hole size is substantial compared to the wavelength of the signal. There are ways to determine the direction a signal is coming from, though. Do a web search on "radio direction finding" or "RDF" and you'll find lots to read.

Whatever you're doing, you might consider investigating the New England Museum of Wireless and Steam (see http://users.ids.net/~newsm/), run by Bob Merriam in East Greenwich, RI. The museum has a large collection of spark gap transmitters, including the entire original Massie Wireless Telegraphy Company "PJ" station, and the museum's volunteers have considerable experience with them.

3566. Mercury Wetted Relay as input relay in a linear amp ?

I have a nice looking flat pack mercury wetted relay made by
CP Clare (HGJ2MT54211P00) that I'd like to use as a
reed relay in the input circuit of an amplifier. Any idea if this
would be suitable, being that it has a lot of metal for the case?
It is a 24 or 28vdc and since it is mercury wetted I assume it
could handle 100w without trouble. Anyone knowanything
about this relay ????

well, the problem is solved on this side, I don't see it as a problem
any more, and my solution was described in the first poster.
My intention was to have the program changed to include links
consisting of less than full loop diameter

In my case the coupling loop has only half the diameter of the large
loop, which means the area is 1/4 of the larger loop, and the coupling
is 1/(4*26) which is almost 1/100, and the transformation is 1:10000.

The 50 ohm feeder impedance is transformed to 500K

I don't see any reason for using an amplifier as the signal output is
still much higher than the receiver noise, in fact the S-meter peaks
6-10dB from the bottom when the loop is tuned to resonnance, on FT-902
this means the signal into the HF transceiver is in the microvolt
region and could well have been at least 20dB lower without causing
any suffer.
I use MC3356 as S-meter detector for FT-902, but the sensitivity was
set to 2 V because of some unknown signals where it was connected.

It would only work for GHz frequencies. Openings bend waves. The lower the frequency and the smaller the opening, the more it's bent. This happens for pond ripples, sound, RF, and even light (CD rainbows are the obvious example).

Take a look at how Yagi TV antennas are built. Only signals going in the proper direction will be received. Everything else cancels and is reflected off grounded poles.

Lower frequencies require multiple antennas and phase detection, unless you want a monster Yagi aerial.

Hi,

RF, of a wavelength greater than the diameter of a tube,
will actually propagate down it but with considerable
attenuation as with a waveguide operating below its cut-off
frequency. The technique has been used in signal generator
attenuators where an output coupling coil is slid in and
out such a tube with an oscillator (sometimes something as
large as an 807) pumping the power in at the other end. If
I remember correctly, attenuation is proportional to the
log of the separation which then enables the dial to be
directly calibrated in dB.

Cheers - Joe, G3LLV

3572. Sensitivity of relative fieldstrength sensor/instrument at increasing frequency

Newsgroup: rec.radio.amateur.homebrew

Recently at a radio club junk sale I acquired a very handy 'RF clip-on current meter' ,for example to check the (relative) current in radials associated with a vertical antenna.
Inside are just an inductor (no toroid) a (germanium?) diode and a pot meter
I noticed that when clipping the device onto a rubber duck antenna of a hand held 2m/70cms transceiver, the meter deflection at 145 MHz is much less compared with operating at 430 MHz with the same RF output (with the potmeter in the same position)

The same effect exists when holding the said transceiver near a SWR meter (labelled 3.5 - 150 MHz) which has a short whip antenna , such that the instrument can also serve as a relative fieldstrength meter.

I should add that in both instruments the moving coil meter is RF shorted by a ceramic disc capacitor (which perhaps is NOT effective at UHF frequencies?)

Perhaps someone can explain why the amount of RF energy picked up by these 2 sensors/instruments increases at increasing frequency and at frequencies well beyond their normal operating range.

Frank gm0csz.kn6wh@ntlworld.com

Frank, putting things simply, the pickup coil (inductor) is closer
to a wavelength at 450Mhz (about 70cms) than it is at 144Mhz (about
2m) therefore it picks up more RF.
This is'nt strictly true, but its probably easier to understand.

Hi Roger,

2.4 GHz EME is sparsely populated. You would be much better off to pursue 23cM EME. With even a small dish (12') it is not unusual to hear guys ragchewing on SSB.
You will need a minimum of 100W at the feed. We use circular polarity, so Faraday rotation is not an issue. Typical LNA NF's are as low as 0.2dB.
Do a Google search under Moon-net, and pick up copies of the ARRL Microwave Project Manual And UHF/Microwave Experimenters Manual.

I currently run 250W at the feed to a 14' surface- echoes are very readable on SSB and CW.

GL,

Dale W4OP

Finally someone explains how the close in tool works for t-hunts. Yagis or loops work fine at a distance, but for the last 100 yards or so, the preferred tool around here is a sheided tube that you lower your handheld into, the distance down the tube determines the attenuation. That close to a transmitter a yagi would be swamped by signals and reflections.
thanks, John.

-- "J M Noeding" <
> Wonder why it is "always" mentioned to use a series coil to tune out
> the capacitance of the 136kHz aerial, instead of more normal sort of
> matching - using T- or L-network

There's no difference in principle between a bottom-end loading coil and an L-network. They both consist of an inductance in series with a capacitor. But the bottom loading coil, all by itself , can only be adjusted to cancel (tune) the aerial capcitance. It cannot produce a resistive 'match'.

With an L-network there's an additional capacitance in parallel with the aerial capacitance to ground, etc. But the load (radiation) resistance is in series only with the aerial capacitance.

The additional capacitor in the L-network allows the aerial resistance to be transformed to another value such as 50 ohms. That's because only a portion of the transmitter current flows through the load (the aerial's radiation resistance).

Without the additional capacitor the transmitter has to be happy with whatever the radiation resistance happens to be. The poor thing has to grin and bear it. (Nit-pickers Roy or Cecil will now have to supply a correction by saying transmitters don't have feelings. Only people have feelings. ;o))

The loss in the coil is smaller when there is no additional capacitor. In the case of the L-network the coil has to carry the current in both aerial AND additional capacitor.

The L-network cannot always match the antenna input resistance to 50 ohms. For example, this can occur when the impedance looking into the antenna is not a capacitance but looks like another coil.

But a T-network with its second capacitor can cover a wider variety of aerial impedances. It has three knobs on the front. And because the circulating currents inside the T-match all flow through the coil, the T-match is always less efficient than the L-match for the same radiation resistance.

T-matches are used by lazy people who dislike having to go outside in the rain to change the length of the feedline when changing from one end of the band to the other. Automatic T-matches are used by VERY lazy people. I have one.

Add me to the nitpickers :)

An L-network can match anything to anything. An L-network is two
reactances, one series, one shunt. The shunt can be on either the load
side or the source side of the series element and the elements can be
any combination of reactances. Two L's, two C's or one of each.

There is always a solution, not always a good solution, but a solution
nevertheless.

So David, now that you've gotten lots of responses telling you to not even think about doing the experiments, could you please tell us more about what you really want to accomplish? Why spark?? Do you understand that, basically, the spark is a switch and not the "source" of the RF? You can for sure learn a lot by shock-exciting the same set of tank components at much lower power, using an electronic switch. Also, as the site that Roy mentioned points out, the antenna itself is an integral part of the resonant system, so you almost certainly won't get the same results with a "small loop" antenna as you would with a full-size antenna.

And for that matter, you can see a lot just by simulating. It's not hard to do a Spice (or similar) simulation of a spark transmitter, and if you like math exercises, you may even be able to do it analytically with linear components.

There have been some good articles in Electronics World+Wireless World over the years on the early days of radio, including some nice explanations of spark transmitters. Have a look there, in addition to Roy's reference.

Cheers,
Tom

So...Dino or someone else...can you post the details of the FMT?
Frequency, time; how long will a carrier be provided?? I certainly
agree that it will be a lot easier for folk near the transmitter, but
it might be interesting to see what those of us who are undoubtedly
far from the transmitter can do. But it will be very helpful if the
signal is there for more than a second or two at a time.

My experience tells me that on HF, the accuracy of the standard isn't
really much of a problem, it's the propagation that will limit the
overall measurement accuracy. Also, I wonder what the phase noise
characteristics of the transmitter will be...how broad will the
transmitted signal be? Will it be just one of the standard ARRL
transmitters?

Cheers,
Tom

Source record: 40148

Tom---Here's the info from the ARRL web site:

The first W1AW FMT will run on November 7, 2002 at 0245Z (November 6, 2002, 9:45 PM ET). It will replace the W1AW Phone Bulletin normally scheduled at that time. It is recommended that participants listen to W1AW's transmissions prior to the event to get an idea on conditions to see which band (or bands) will be best for measurement purposes.

Format

The FMT will begin with a general W1AW (QST) call beginning exactly at 0245Z sent simultaneously on four (4) amateur frequencies. The test will consist of 20-second key-down transmissions, followed by a series of dits, followed by station identification.

The test will last for a period of approximately five (5) minutes total. The test will end with a series of V's, followed by station identification. W1AW will identify before, during and after the transmissions.

The approximate frequencies are as follows:

80 meters - 3580 kHz

40 meters - 7047 kHz

20 meters - 14048 kHz

15 meters - 21068 kHz

Reporting and Results

The submitted report should include the time of reception, frequency measured and signal report, in addition to name, call and QTH. If possible, participants should submit reports on more than one band (but not necessarily on all four).

A Certificate of Participation will be available to all entrants. Those entrants that come closest to the measured frequency as measured by the ARRL laboratory will be listed in the test report and will also receive special recognition on their certificate.

Entries should be postmarked by December 6, 2002 to be eligible. Send entries to:

W1AW/FMT
225 Main Street
Newington CT 06111

Equipment to be used for the 2002 W1AW Frequency Measuring Test

Transmitting Equipment:

* Harris RF-3200 Exciters w/ Harris RF-3220 Solid State Amplifiers

Antennas:

* 80-meter cage at 60 feet
* Phased 40-meter yagis; 65 feet and at 130 feet
* Phased 20-meter yagis; 35 feet and at 70 feet
* Phased 15-meter yagis; 45 feet and at 90 feet.

CW Generation:

* Compaq 133 with DRSI packet card (used to control matrix)
* ARRL Laboratory-designed Keying Matrix (keys all exciters simultaneously)

Measuring Equipment:

* Hewlett Packard Z3801 GPS Receiver/Frequency Standard (provides 10 MHz reference)
* Optoelectronics 8010 Frequency Counter w/ 10 MHz signal reference
* (QST Product Review)
* Dunestar Bandpass filters
* Alpha/Delta switches

Have fun!!!

Source record: 40149

Assorted comments, not necessarily in reply to Dick's posting but
covering some other points in the thread as well:

I view d'Arsonval meter movements to be sensitive to _current_, not
power; you have to allow for change in internal resistance, but the
response to current should be proportional to the magnetic field and
inversely proportional to the restoring spring constant. Both of
those _may_ change noticabley with temperature. But I suppose a
proper shunt for a copper-wound meter would be made from copper as
well. Then the current sharing will remain in a constant ratio, if
the meter and the shunt are kept at the same temperature.

Over the weekend, I measured several old d'Arsonval meters against a
Fluke 4.5 digit DVM and another 3.75 digit DVM I have; I occasionally
check the Fluke against my HP3456A at work, so I think it's pretty
close...closer than I can read the meters. Not one of the meters was
as much as 2% off at full scale. A couple with mirrored scales,
individually calibrated, were as close as I could read them. This was
done at very close to 20C; it might be interesting to try it at 0C and
50C. The meters ranged in age from about 15 years to over 50 years.
They were from assorted manufacturers: GE, Simpson, "Micronta"
(whoever made them for Radio Shack), Weston, and whoever made them for
HP.

Cheers,
Tom

3588. Re: Matching Network for an LF inverted-L-antenna

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-11-04 19:47:23 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <usdjm71a44p315@corp.supernews.com>
Source record: 40150

A slight clarification. There isn't a *single* L network that can match anything to anything. (I know Wes didn't mean that, but what he wrote might possibly be interpreted this way.) It's just that an L network (actually, usually two) can be designed to match two given impedances. From one situation to the next, you might need a different combination of Ls and Cs, as Wes says. And in some cases the shunt element has to be on one side of the network and in other cases the other. And in some special cases one element or the other isn't there at all.

Roy Lewallen, W7EL

Guys, a reality check is in order here.

If the guy cannot use a scope, he is unlikely to posses the necessary
technical knowledge to correctly build and aliign such a mixer.

That said, there's nothing like doing a job beyond one's abilities to force
the aquisition of skill and knowledge

Hi Wes, You do yourself an injustice. The point you raise is not trivial and should have been mentioned in my light-hearted rambling. My omission could have been misleading.

==========

> An L-network can match anything to anything. An L-network is two
> reactances, one series, one shunt. The shunt can be on either the load
> side or the source side of the series element and the elements can be
> any combination of reactances. Two L's, two C's or one of each.

==========

There are in fact 8 members of the L-network family (2 cubed). But from a practical point of view, in the black box with only two knobs on the front we are restricted to only one of them. An array of switches is needed to select any one of the eight possibilities. And the box must also contain two L's and two C's. This is of course uneconomic because only three components are needed for the more flexible (but less efficient) T or Pi networks.

When considering the whole gammut of possible antenna impedances relative to 50 ohms, provided the direction of transmission through the box can be reversed, one L and one C will cover a large proportion of the possibilities. The restrictions, as always, are practical ones - minimum and maximum settings of the variables.

Anyone interested in numbers but dislikes arithmetic could download (in a few seconds and run imediately) program L_TUNER from website below. It has a companion T_TUNER. These programs indicate when impractical component values arise.

They are of use when peculiar antenna impedances are known and matching-network component values are needed. On such occasions human imagination fails. This frequently results in questions on these radio newsgroups.

Personally I prefer home-brew L-networks. No knobs - just a handful of alligator/crocodile clips. Some years back Roy once went to much trouble to describe to me the anatomical differences between animals which have seperately evolved in Florida and Egypt, from which beasts the names of clips have been derived. But why some clips get hot enough to sear the skin

off thumb and finger tips when connected to tank coils, and others do not, I have never discovered.

Jan-Martin asks such deceptively simple questions. I think he does it intentionally. ;o)

3592. Re: Mercury Wetted Relay as input relay in a linear amp ?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-11-04 22:36:45 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <aq6spshhg2@helle.btinternet.com>
Source record: 40155

Been a long time since I had much to do with mercury-wetted relays. But I don't think their power handling abilities had anything to do with their applications.

They were often used in high-speed data-handling circuits and suchlike. Contact bounce was eliminated. There was no probability of self-sealing contacts at microvolt signal levels. Absolutely no noise. Insignificant contact potentials.

Conclusion - use in reliable, low-noise, high-speed, very-low-signal-level circuits. Radio receiving antenna circuits ? Low-noise amplifier inputs ?

Some types could not be used at all orientations because the small mercury reservoir could run to one location inside the bulb and short-circuited the lead-in wires.

Mercury found its way to the contacts by capilliary action along the contact blades. The surface of the blades was etched in extremely fine cross-hatched grooves to facilitate capilliary action.

I remember using them at 20 or 30 Hz switching frequences for comparison of signal levels of a few millivolts. These were Clare relays around 1960. Is this manufacturer still in business then ?

Reg.

Why not just measure WWV or WWVB. It's always (almost) available, you KNOW where it is both in location and frequency, as well as it's published accuracy, so you can determine yourself how close you can come to the actual frequency. Any time, any day, depending on prop to your location. Seems like a waste from here to measure someone's secondary standard, provided for extremely short averaging periods.

From: Frank Dinger <gm0csz.kn6wh@ntlworld.com>
Message-ID: <5CDx9.50$T21.62069@newsfep2-win.server.ntli.net>
Source record: 40160

I have 8 toroids with an outer diameter of 90mm (3.5 inches) and an inner diameter of 57mm(2.5 inches)
With 4x2pairs positioned in a square ,they form a balanced to balanced sort of antenna choke.
The toroids are marked with a white and a red painted dot.
Is this colour coding indicating a specific type of 'powdered iron mix' or a type of 'ferrite'.

It is my intention to use a pair for a 4 : 1 (Ruthroff design) balun .
I do have Jerry Sevick's (W2FMI) book : 'Building and using Baluns and Ununs
'

TIA for any advice re colour coding.

Got his 1937 "Radio Engineering" for 1.0 UKP. Altogether rather
tedious. Much more informative was Ulrich Rohde's 1988 "Communications
Receivers" at 1.50 UKP.

I rather enjoy Terman's "Radio Engineering" because it is a good college level text-- someone in Electrical Engineering on the GI bill just after the war would be studying this book. I have pre-war and post war editions. The post-war information makes the editions a lot larger. My latest edition even has transistors in it.

The Radio Engineers' Handbook is good for quick answers when you don't need to know why and how it works. Radio Engineering is a better read.

...etc

Thanks Dino!

At about 7:30 this evening here in Western Washington, which is about 45 minutes past the time-of-day of the test, I could receive W1AW well enough to make a decent measurement but only on 40 meters. They were pretty weak on 80 and 20. I'll probably concentrate on 40 for the measurement.

But also, WWV was pretty wide at that time, which is understandable, since it's not too long after sundown. WWV on 5, 10 and 15MHz all showed a double peak, spectrally, and were on the order of a couple Hz wide. The double peak is most probably WWV and WWVH, but they weren't very distinct and also weren't very stable. Not good conditions to make accurate frequency measurements! In the middle of a stable day here, WWV will be a fraction of a Hz wide, and you can be pretty sure of nailing the frequency to a part in about 10^8...that's better than they recommend, but I don't think their recommendation assumes you'll have equipment that can tell you that much detail about the spectrum. Based on what I saw on WWV and also on W1AW, I don't expect to be able to find the FMT frequency much better than 1Hz.

For comparison, a TV visual carrier up around 77MHz was around 1/10 Hz wide, and AM broadcast carriers could be resolved down to better than 1/100Hz, given enough measurement time. But the measurement time doesn't help much when the propagation broadens the signal.

Cheers,
Tom

With a little help from the group, I was able to figure it out. The operation is a lot less complicated than I thought. I re-read the manuals and everything was clearer. This is one nice unit! I'm able to see all kinds of signal phenomena with it.

You could with a Ferrite antenna working in the short-wave band; Radio
Amateurs use the term "Fox Hunting".

The signal from the ferrite antenna drops very sharply when the ferrite is
pointed at the source, so you search for "nulls" in the signal. A map and a
compass helps too.

The K2 does have a squelch control.

The threshold can be accessed and set from the menu system, and it is nice
to use for instance when scanning. But it can of course be used any time the
radio is on.

From: gc@radix.net
Message-ID: <aq95tg$o2b$1@news1.radix.net>
Source record: 40175

I have been working on getting ready for the FMT over the past month.
It has been interesting having an excuse to get out some of neat test
equipment that I have acquired and make some actual use of it. Making
accurate frequency measurements is not a big deal these days, but measureing
frequency for an HF signal over the air is a bit more effort. This has
also provided a topic of discussion on the local repeater during
morning drive time.

In article <20021103133721.25072.00001377@mb-dh.aol.com>,
Dino AL7LZ <dinoal7lz@aol.com> wrote:
>You can attempt to account for the propagation error by monitoring the standard

>approximately the same time the test will be conducted. If the radio you use

This is interesting. I didn't know that ionospheric variations correlated
over different paths that well. From my location W1AW is northeast
and WWV is west.

>accepts an external reference (the HP Z3801A for example) and you offset your
>BFO (also locked) to a known value you can then measure the frequency of the

>happens.
>

That's about what I planned to do. Good thing I started early, as
that receiver quit on me. Now I am feeding a RF signal into the antenna
to beat with the received signal, then measure RF signal generator and
the audio beat note. This works with any receiver, but requires
a stable signal generator. I am hoping for better than 1Hz.

I don't know what a K2 is, other than an HF rig, but most of the newer rigs
have squelch. The Icom 756 Pro does and "I think" the Yaesu. Not sure about
Kenwood.

>compass helps too.

If the whole purpose of the original question was fox hunting, then
the choice could be a loop or ferrite/iron-powder core antenna for
HF and a multi-element Yagi for VHF and higher. This has been
documented in amateur radio literature.

As has already been pointed out, a metal tube is a "waveguide
below cutoff" attenuator. Such attenuators were quite standard in
signal generators for years, even in precision attenuation standards
made by Bruno Weinschel. For distances of a "few hundred feet"
or about 100 meters, the directionality might be useful if the metal
tube is not too long (offhand guess is about a third of a meter?).

The EM theory behind all of this can be quite complex. It has to
take in the inside diameter of the metal tube, its length, the
signal frequency. The opening of the metal tube will be, in effect,
an "aperture antenna" of sorts and its characteristics would depend
on the physical dimensions and frequency. Note: So-called "slot"
antennas have been used on aircraft and spacecraft for decades
where the antenna is just a slot or other aperture in a continuous
metal plane. RCA Corporation made a waveguide slot antenna
array that replaced their conventional metal cloth in fiberglass
parabolic X-band commercial general aviation radar...it was lighter
and more stable.

The origin of the question might lie in the similarity to a "shotgun
microphone" used for very directional audio pickup at sports
events on TV. That one can be a series of different-length tubes
bundled together (for broad-band audio). Those tubes don't have

to be metallic.

Whether or not such a directional antenna could be made can be solved by a simple experiment. Get a length of metal tube or some ABS plastic waste line pipe. If ABS, run some aluminum cooking foil the length of it with edges overlapping. Insert receiver or small probe for same in one end. Find a signal source at a nearby location and see if it is directional...or even if it can pick up any signal. It may not...or it may. This takes far less time than trying to go into all the theory of fields and waves and necessary calculation.

[ABS = Acrylonitrile Butadiene Styrene, stiffer than PVC water pipe and sold in USA do-it-yourself stores usually dyed black]

The waveguide-below-cutoff effect has been used to reduce EMI from large metal chassis and panel apertures...especially so in front panel meter holes where the cure was a three to four inch metal tube around the meter body behind the panel. That was good for an additional 20 to 30 db of attenuation versus the un-shielded meter hole.

Intersting. I have an early 1930s copy of a 2-inch thick book called "Radio Physics". Much of is is still amazingly still relevant. Another one that dates from around 1938 is called "Mathematics for Radiomen". Interesing title. Now here in Canada, that title would get half the population whining about sexism, and one would be pressured into callinng it "Mathematics for Radiopersons".

Bob.

Fifty years later would be 1993. Are you saying that the state of radio engineering in 1993 was just catching up to 1943 Europe? You're a bit of a lame-brained ass aren't you?

The story in the years between has been a sad one, as you'll see from the web site. After having been asset-stripped, the company has now been rescued and seems to be in good shape. Many of the products are back in stock, and JB are also making 'specials' which are not in the catalogue, such as large bandswitches.

A pity about the prices, but that's what metal/ceramic components cost these days. It's much better to have them available at some price than not at all.

BTW, large transmitting variable capacitors are also available in the UK from Nevada and Linear Amp UK.

I might, if I can find one that comes with a full manual and schematic.
Don't know about the amp. Power can be expensive at 2.4 and above.

I have in my possession in good condition the book -

"Wireless Telegraphy and Telephony" by Prof. Domenico Mazzotto.

Translated into English from the original Italian by S.R.Bottone.

415 pages including 253 illustrations, circuit diagrams, beautiful drawings
and photographs of equipment and aerials.

Published by Whitaker & Co., 2 White Hart Street, Paternoster Square,
London, E.C. in AD 1906.

==========

From the preface by the translator -

"Prof. Mazotto has executed his task so thoroughly as to leave no important
facts or theories connected with Radiotelegraphy unnoticed; and has clothed
his thoughts in language at once so simple and so forcible, as to render the
comprehension of the subject easy to the merest tyro."

==========

I am in my 77th year. What should I do with this book?

Small company called Elecraft out in Aptos, CA. Modular design starts out as a basic QRP CW rig to which you add whatever options you desire - noise blanker, SSB, 100 watt final, audio filter, ATU, internal battery, etc. Even the basic unit has lots of features and high performance. And it's a kit!

Hi Folks, a simple query.. ;-)

rotators like the CD44 and Yeasu KR series use an AC supply of 26v.
What I would like to know is the ballpark figure for current that they
draw under maximum load or inital start conditions. I've got a KR600
for which I need to build a controller and I need to know what
transformer and switch rating to use before I start construction.

thanks Mike W

Yes ... I turn first to the old books if I'm after something really
basic. They tell it as it is without having to wade through endless
modern discourses on electron physics etc. (this was a time when 'men
were men').
Had figured out a method of electrolytically etching PCB's using a
stepper motor scanning arrangement and pumped electrolyte. Needed
Faradays electroplating constant. First port of call was Ayrton's
1898 tome on 'Practical electricity'!.

> transmitters?

Just for fun I checked the W1AW CW signals yesterday two or three times during the afternoon and
evening. The doppler shift, (or should it be phase shift more correctly?) was of the order of 1 Hz
maximum on the 40, 20 and 15 meter signals, here in southern California. There is also some slight
frequency variation over the course of a code element of that order, I hesitate to call it chirp :^) I
don't know how one could separate any possible spectral impurity from this kind of effect.

Given that a lot of folk now have the capability to measure off air down to fractions of a Hertz, to
reach the maximum accuracy, we will need a lot longer time to average out a number of measurements than
the FMT provides, in it's current form.

FWIW 7,047,533 1642 local 7,047,521 at 1930 local
between 14,047,532 and 14,047,534;
21,067,531 and 28,067,486 Hz, were the numbers.

(Racal RA1792 Rx, frequency measuring version, Racal 9475 Rubidium set from GPS)

Cheers
Dan ac6ao g3ncr

Hi,

When you read the semiconductor physics in the "MIT Radiation Lab" series, and with the realisation that the theory went back well before the start of WWII, it makes you wonder why it took Bardeen, Brattain and Shockley so long to connect the 'third' wire.

Factoid : William Shockley was born in London in 1910.

So that's were he got it all from!

Cheers - Joe

It also depends on how the relays are constructed.

If the coil is wound so that the contacts pass through the center of the coil, the coil will act like a choke at RF---signal goes in, nothing comes out.

I learned this the hard way many years ago when I was a Novice Class, except I was trying to use a reed relay on 2 meters. The kind with the contacts outside the coil would probably work, but the ones I had had the coil wound around the contacts.

With the mercury relay how what would the HV RF do?

Golly Moses, are you not aware that nearly every one of them is 95%
shielded by up to an inch of steel or aluminum, then additionally 80%
shielded by thick sheet metal? Are you not aware that they don't run
a continuous spark, but pulsed on a very low duty cycle? Are you not
aware that there are no antennas connected to them (the spark plug wires
don't count, they're dummy-load resistors)?

They don't. Using spectral analysis, at certain times of the day, I
can resolve multiple peaks on 10MHz or 15MHz. I'm quite sure they
come from WWV (to the SE from me) and WWVH (to the SW), and smaller
ones (generally down 30-50dB from those two) come from other stations
transmitting time and frequency reference signals, or from distinct
separate paths from WWV/WWVH. In fact, a bit after sunrise here, I
can typically see one peak on 10MHz +/- 0.05Hz, presumably WWV, and
another perhaps 2Hz higher, presumably WWVH.

I wish I had a friend in Hartford that could transmit a known-accurate
frequency at the time of the FMT. Failing that, CHU will have to
suffice. It's at least in the neighborhood of Newington, relative to
where I am.

For Harold: of course, it's simply for the fun and/or challenge
(and/or ??) of doing it. Why do people climb more than one mountain?
Why do people climb a given mountain more than once?

Cheers,
Tom

And I thought the newsgroup was for amateur radio, not the job (?)
I used mixers and other solutions with my Telequipment D52 5MHz scope
to check signals on 432 and higher. And I was told that OZ2BB
reconstructed some of his transmitters after reading my notes on using
mixers ahead of oscilloscopes around 1985

Allow *any* 2nd hand book seller to acquire it. They *will* look
after it because it's relatively old. Someone like me will then spot
it from about 10 miles away, take it home and subsequently treasure
it, until in turn, my time comes and the process can then repeat.
The trick, is to know that these book sellers do really love and
appreciate good books (even technical ones!).
regards
john

>Are you not
>aware that there are no antennas connected to them (the spark plug wires
>don't count, they're dummy-load resistors)?

Hi Cliff, Of course I am aware of all that, I used a spark plug as an example of a spark transmitter that won't wipe out radio receivers all over town. On the other hand I remember 1950s vintage Fords that put out a good signal in excess of 100 yards. You could always tell when one was going down the street if you had on the am radio, or bw TV set.

I was responding to advice not to build a spark transmitter because it will interfer with all types of necessary communications. Certainly a spark can readily do that, as can an improperly built tube or solid state transmitter. All depends on how you build them, where you put them, and what kind of antenna you plan on using.

> (and/or ??) of doing it. Why do people climb more than one mountain?
> Why do people climb a given mountain more than once?

Dunno, that always seemed kind of silly too. (Apologies to Edmund)
Personally, I still think I'd get more pure satisfaction out of measuring something, making my own determination as to how close I was, instead of taking someone else's word for it, and thinking about whether I could improve or not. Of course, NEEDING to improve is another ballgame. I phase lock to WWVB maybe once or twice a year to lock my Austron down. That's my clock for the shop counter. Suspect it's probably an order of magnitude less accurate than what you and Dan do, KNOW it's about 3-4 orders of magnitude better than I NEED.

In the grand scheme of things, and given a finite lifetime, we all have to assess what's important to ourselves. I never heard anyone ask at 1FB's memorial service "How close did he ever get in the FMT"?

Regards

W4ZCB

Well, I was thinking of one of the Yaesu's, I think it was the FT10000D or something like that (I'm not really up on them), based on Adventure Radio Society's excellent lab comparisons. In fact, the ProII was very close, and everything else was far behind those three. (But I haven't seen their results for the new TenTec).

Have a look at www.pcb-pool.com they let you download full version
commercial windows software (and are cheap at RF boards)

Used them for a Uni project, excellent quality.

3653. K2 Transceiver Completely Updated!

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-11-07 00:15:40 UTC
From: Eric Swartz WA6HHQ - Elecraft <eric@elecraft.com>
Message-ID: <3DC9B0AC.BDF4F336@elecraft.com>
Source record: 40117

We're pleased to announce we are now shipping a major update to the K2 transceiver (and K2/100), starting with serial number 3000. We have been shipping this version for a couple of weeks and all new orders will receive it. If you've been waiting to buy a K2, you'll find many new reasons to take the plunge. If you already own one, you'll be happy to know that you can also obtain a complete update kit. (Please hold any e-mail or phone calls until we post additional details on the update kit later this month.)

Designs evolve, and the K2 is no exception. During Elecraft's first three years, K2 owners suggested a number of useful changes, and we've added nearly all of them into the updated kit. (We'd like to express our appreciation to everyone who helped with these improvements.) All modifications that were required for the installation of K2 options have also been added.

The updated K2 offers new features, improved basic performance, and simplified assembly. The most important changes are listed below. These changes make the K2--already one of the highest-performance ham-band transceivers you can buy--an even better value.

New Features and Performance Improvements:

-All of the most-requested modifications now incorporated into the design
-Improved temperature stability; includes new pre-wound T44-7 BFO inductor
-Increase in nominal receiver gain possible using new AGC threshold control
-Improved image rejection on 17 through 10 meters
-Better LSB/USB pitch matching and flatter 2nd I.F. crystal filter
-Smoother AF GAIN control
-More pleasant sidetone sound
-Speaker grille cloth supplied
-Support for KAT100 150-watt ATU
-Support for upcoming K60XV 60 meter/low-level transverter I/O option

Changes that affect Assembly, Alignment, and Operation:

-Complete RF probe kit now included (switch spacing tool now doubles as RF probe PCB)
-Many improvements to PC board layouts; all required or recommended board mods added
-Crystal filter grounding instructions improved to increase ultimate rejection
-Owner's manual completely updated based on suggestions from builders
-Operation section of manual now covers all recent firmware features, including all entries in the secondary menu

Other Changes/Enhancements:

-Reverse-polarity protection diode is now ultra-low-drop type (only 0.1V in RX mode)
-Improved FINE RIT resolution and better tuning linearity on highest bands
-12 pF caps in parallel w/20/30 BPF trimmers eliminates 20/30 alignment difficulties
-Post-mixer amp collector choke is now a toroid, reducing unwanted S-meter activation from out-of-band signals (most often reported on 17 m)
-VFO ALC changes included (in support of KPA100)
-Voltage source selector switch on Control board is now a jumper--eliminates unexpected "0.0 V" reading in voltage/current display mode

Those are called crystals and not channel elements. Channel elements buy
you a temp comp that gives you 5 ppm or better. You can't get that with a
crystal by itself even if you team it up with a matched tc cap. The CE's
for both the MT and MX radios were cascode Colpitts oscillators and
included warp and mod sense tuning coils. If you don't believe me, rip
one open and look. If you're careful, you'll do no harm. I would be
willing to bet that the transistors will be M9570's also. You also may be
referring to mobile CE's which may have had all kinds of stuff in them
other than just the crystal and tc cap. I can't address what mobile did.

I'm trying to find a source for high quality microphone cable, 2-3 or 4 conductors, shielded, flexible, and easy to work with. Have found sources that sell it in 100-500 ft spools but that is a bit too much.

Thanks for reading the posting.

Evan

Evan,
We sell some really nice shielded microphone cable (custom made for us) in 10 ft minimum length. As you asked, it's very flexible and easy to work with.

Check out our website at: www.ncsradio.com and go to the Accessories page.

I have a fond place in my heart for Ten-Tec. I've used a lot of their
equipment over the years. I was also a dealer back in the 70s. That final
is rugged. I used to loan out an Omni or two for events. I only lost one
final in those years and I only had one customer lose a final. (Not sure how
he did it).

One group wanted to run 15 meters, but didn't have an antenna cut for 15 or
a tuner. I told them to try the 40 meter dipole (3rd harmonic) and if all
else failed use their 20 meter to see if it would work. The 40 meter
antenna worked fairly well. The 20 was nothing to brag about, bit it did
work. the rig was still working fine when I got it back.

I'd like to set that 565 next to my Icom. If it's anything like the earlier
rigs it's going to be great on QSK.

Yeah, well, I'd hope nobody asks anything like that at mine either!

Of course, for me, it's also related to the work I do. I don't view the transmission (and especially as received) as one frequency, but rather as a spectrum, and I'm always curious how well our equipment can measure that spectrum. Here, tonight, W1AW's spectrum on 40 meters was decent, and the one on 20 was really ugly. I'd say their spectrum on 20 was significantly worse than what I saw for CHU on 14.670, at similar signal level.

Cheers,
Tom

Hi all,

Anybody who can guide me to / provide me with a datasheet of
the old COP8782C microcontroller from National Semiconductors...???

Nothing is available on the National's homepage and my Internet
search gave no usefull results...:-(

Also, I would be very much interested in circuit diagrams for a
programmer for these devises.

Thanks a lot in advance.

Well, that's a relief. It appears to indicate that it's a path thing as opposed to a phase noise in the TX thing. Or else they're using two different rigs for the two bands and one is really lousy. Back to the soldering iron.

Does anybody have alignment notes for this unit. I picked it up at the Rockwell sale last Wednesday, and it doesn't seem to work. I did measure the gain of the output amp at 20dB, so it seems that this stage might be working, but the variable output control doesn't work. This unit should work with the 8558B Spectrum Analyzer. Am I missing something here? Thanks for any info.

The whole KR600 control box is rated to consume 40VA max, so a 26V
1.5-2A transformer rating should be fine (or even 1A, since it's only
intermittent service).

There's a full manual at http://www.logsa.army.mil/etms/find_etm.cfm
Search for 8444 in the ETM box.

No charge - you already paid for it...

Possibly.
The 8444 needs to have Option 059 installed to work with the 8558. (and the coax link at the back needs to be in place) Otherwise there is not much to go wrong or adjust, only the frequency of the free running 1500 MHz oscillator; this is tricky to do, so unless the tracking control is at one extreme or other, it's probably best left alone.

You can probably get a manual from: Ed Matsuda (ematsuda@earthlink.net)

Hi,
a 40VA transformer is common in many rotators (YAESU G400 and up,
DAIWA DC7011 etc etc..)
24-26 VAC is the voltage needed for the motor..
1-2 A should be OK!
ciao

I have had received some sensible ideas and enquiries on how to dispose of this book. It seems it is of more historical/technical interest than I realised.

Where I DO NOT want it end up is on a collector's bookshelf where nobody except the collector ever sees it, who doesn't understand it anyway, and nobody else ever has the opportunity to read and enjoy it. Even learn from it.

It would be a disaster for it to end in an ignorant house clearer's incinerator.

Thank you all for your suggestions.

No, they are called channel elements. For example, in the Motorola Micor line, the only element that was active element was the KXN1019, which
was used in the direct FM exciter base stations. The receiver channel elements, and the phase modulated exciter channel elements, were passive. The same receive channel element was used for the both the mobile and base models. The old Motran elements may have been active, as you noted, but my memory isn't that good.

Ron,
Thanks for the tip on the FX335. I had found a data sheet on a
different CML device
earlier, (the MX165C). FX335 seems very easy to work with. The data sheet
even give
a good suggestion on how to apply it.
Since you have used these before, were do you get yours. The more
traditional (Digi-Key
and Mouser) do not carry them. Does CML sell small quanties? I have not
had a chance to
call yet.
Also do you make your own PC boards or do you use one of the on-line PCB
houses?
Thanks again for your input to my question.

Norman

If you find a transformer for the 6.3 VAC, get two, connect them
secondary to secondary, you should get about 170 Vdc from the primary of the
second transformer after rectification and filtering.

3687. FS: HV Rectifier Modules for Linear Amp PS

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-11-08 14:37:10 UTC
From: GaryH <garyh@bellsouth.net>
Message-ID: <NWPy9.4861$ds6.680@news.bellsouth.net>
Source record: 40050

I have 4 diode blocks for a HV power supply for a large
HF amp. I don't have the rating but believe they are
10 KV modules based on the size. I took them out of
a Large amp that I restored to stock diode configuration that
used three 3-500z tubes and a 3500 volt plus power supply.

I suspect they are 1 Amp rated. They are 3 3/4" long, 1" deep
and at the highest point, 2" high with screw terminal on each end
and polarity marking on the bottom. They are ideal for a homebrew
project or upgrade the diode bridge on an existing amp. I can
send you a picture if you are interested. These are quite expensive
if purchased from RF parts etc but all I am asking is a reasonable
offer for the 4 modules.

I have been posting such items on Ebay but have been asked to list
items on newsgroup first. If no reasonable offers are made I will
place them on Ebay. Check my ebay feedback for proof that I
only do up fron deals. Ebay id is garyh@bellsouth.net.

Thanks

Gary K4MT

the
> second transformer after rectification and filtering.

Excellent idea . But please check 6.3 V winding rating of the transformer
connected to the 117V supply system.

For 150 to 170V @ 50 mA the second transformer needs to supply (150 to 170)
* 0.050 = 7.5 to 11.5 Watts ,so the 6.3 V winding rating must not be less
than 2 A in order not to be too marginal
The first transformer 's 6.3 V secondary winding is to supply 1 A for your
valve filament(s) ,plus 2 A for the second transformer ,hence it needs to
have a rating of not less than 3 Amperes. So you are talking about a 20 to
25 VA transformer.
The second transformer needs to be not less than 15 to 20 VA

I have a transformer that's a little overkill for your requirement, 120 volt primary, secondary bridged gives 150 VDC @ 450 mA and other winding 6.8 volts CT @ 700 mA. If size doesn't matter, it's 3 x 2-1/2 x 3 in clamshell, be happy for it to have a new home for postage.

Hi Norman
I have never purchased a new FX335 as they are common in lots
of surplus PMR equipment in the UK, so I just do a desoldering job!!
The reason I have made up a few is I fit them to Philips 1200 series
PMR trunking radios which do not have CTCSS, with a few other
mods these radios made excellent 2mtr Amateur sets, and the FX335
is programmed by a serial to parallel shift register which I then
connect to the sets internal data bus with modified firmware.
I've made up my own PCB for this, I only use the encode part of
the chip but it can be made to decode very easily..

from Ron....

I am trying to modify a battery powered fm/am radio to recieve 2m. It uses a Sony CXA1691Bs IC. I have located what i think is the Local oscillator coil. Stretching this coil as much as i can (while still keeping it coiled) results in the top broadcast frequency (104.6) being right at the bottom on the 88Mhz mark of the tuning dial. this is not high enough to pick up 2m.what must i do to be able to reach these frequencies?

Another way to do it (but see safety note below) is to use a
transformer with split primaries. Use one primary to drive the
transformer and bridge-rectify one for the 150V output. Actually, if
you use a smallish input filter cap, the average output voltage will
be somewhat less than the nominal 168V peak...which, with all the
rectifier/filter cap loads we put on our lines typically is a bit less
anyway. You should use a transformer with at least 25VA rating.

The safety issue is that there is typically not as good isolation
between the two primary windings of a split-primary transformer as
there is between primary and secondary. But it needs to be good for
240V plus transients anyway, and if the equipment it's in is properly
grounded and fused, it shouldn't be a problem.

Cheers,
Tom

Even if you manage to reach 2 meters, you have a major problem. Commercial FM broadcasting transmits very wideband FM and has widely spaced channels, while all the communication services at or near 2 meters broadcast a much narrower FM signal with much closer channel spacing. What you'll discover is that the audio is very weak, and you'll hear a lot of stations all at once -- likely dominated by powerful paging transmitter signals. If you do want to see for yourself, you'll have to find the capacitor which resonates the oscillator coil and reduce its value and/or replace the coil with one having fewer turns and/or smaller diameter. There'll also be other tuned circuits you'll need to modify.

Many years ago, I tried something like you're doing now and discovered the problems I mentioned. I ended up building a simple converter with its own oscillator, to convert from 2 meters down to the AM broadcast band. An AM radio was used with it, and the audio was adequately loud. (An AM radio will detect a narrowband FM signal by means of slope detection.) But image response was just about nil, and that approach wouldn't be any good these days in an urban environment where there's a large number of strong signals on nearby frequencies. It would be much easier and better to start with something inherently designed to detect narrowband FM VHF signals, like an old Radio Shack Weatheradio or some such.

dL:

Roy makes some good points, although I suspect the 2 meter band may not be as crowded in .nz as it is in the shadow of Portland. Don't imagine a lot of sheep operate 2 meters. Here in the U.S. at least, broadcast FM stations are separated by 200 kHz while 2 meter amateur signals are separated by 15 or 20 kHz (again, here in the U.S. it's 15 or 20 depending on the particular state's plan). Even then, most FM broadcast receivers can't really separate 2 stations only 200 kHz apart - the strongest one will win because of the FM "capture effect".

But because of the deviation, even under ideal conditions you will get only a fraction of the audio from a 2 meter amateur signal that you will from a broadcast station.

The problem will be aggravated somewhat by the receiver's front end. Once you've moved the local oscillator, the receiver will be trying to filter out the 2 meter signals in it's front end. If you hear anything at all it will be only the strongest stations, and the odds are good that stronger stations between the broadcast stations and 144 will swamp the amplifiers, so once having moved the LO, you will then need to retune the front end, something which may or may not be simple.

But, if you are relatively close to a repeater, and I would suspect that except in the largest cities there are probably only one or two repeaters, it may make a useable monitoring receiver. But I wouldn't be expecting miracles.

Remember, as Roy pointed out, besides the L you are playing with, there is a C, and you need to reduce the product of the two. Spreading the turns of the inductor will make a tiny difference. Removing a turn or two will do more, and there will be a capacitor (or several) that could be reduced if a turn on the inductor amounts to too much. I'm guessing that there aren't many turns on that coil and a turn less might put you up around 200 MHz instead of 144.

> Pete, k1zjh

Like I said in my previous post, if it's a mobile it may be passive, but if it's a portable, either MT or MX, then it is definitely active. The output was the collector of the Colpitts which went into the emitter of a common base amp which was external to the CE and was usually buffering a tripler or SRD multiplier on the opposite end. This kept the output impedance of the oscillator high and the input to the amp low making the node low at the output of all the CE's. This made multiple frequency operation easy with little interaction and desense. All you did was to bias on the correct channel and away you go. It was a really smart design.

I agree with Roy - converting down to an AM receiver is the best way to go. An AM-only car radio is best as it's well shielded and sensitive.

Use a xtal frequency multiplying up to around 145.9 MHz - this will give a very useful 146.4 - 147.4 MHz range, including many popular simplex & repeater freqs. The images will be near 145 MHz, so you might get some packet sigs as images. But unless you're unlucky, the images won't fall on a nearby repeater freq.

> and polarity marking on the bottom.
==========
!0 kV in this instance probably means 10 kv peak inverse voltage ,hence max
rms voltage would be 10000 / 2 * 0.7 = 3500 V.
Each module comprises a number of silicon diodes each causing a voltage drop
of approx 0.7 V in forward bias mode.
With each diode normally used for this type of application expected to have
a PIV of 1000 volts you can check the rating by allowing (at a low voltage)
a current of say 50 mA to flow and then measuring the voltage across the
module.
If indeed 10 kV there should be 10 diodes in series resulting in a voltage
of approx. 10 * 0.7 V= 7 Volts .
You then can check the current rating by increasing the forward bias
current to say 0.5 Ampere or even up to 1 Ampere for a few minutes .The
module should NOT get hot.
It is likely that these (usually potted) modules are built with 1Nxxxx
series diodes most of which have a 1A current rating

In the above way I have tested 4 'mystery' HV rectifier modules myself.

To whom it may belong,

I am looking for a possebility to transver data from own PC to an
other via a one-way soundcard to soundcard cable.

mt63 provides this capeability bit is _very_ slow.

I know my question might be a bit off topic but I am that desperated...

Thanks for any ideas,

Ralph Odigio

<no_spam@hotmail.com> writes:

>Is the Omni still available? I've seen pics of it and it looks like a
>beautiful rig.
>
The Omni 6 Plus has been replaced by the new Orion.

"Omni" is the family name of a whole series of Ten Tec rigs, from the "ABCD"
analog PTO versions of the early-mid '80s, to the low noise PLL Omni 5, Omni 6
and Omni 6 Plus versions of recent years. (The "Plus" was the addition of DSP
and some other improvements).

The current TenTec HF line is in three levels - the ~$100 monoband QRP CW
transceiver kits, the $800 Argonaut V 20 watter allHFband multimode, and the
$3300-$3600 Orion super rig.

Argonaut V is obviously meant to compete with the K2 and Orion is obviously
meant to compete with the FT-1000. TT doesn't (now) make a moderately priced
100-watt-class-HF rig.

Plenty of clean used Omni 6s out there at good prices, tho. But I'd rather have
my K2.

3708. HP 5340A vs HP 5342A?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-11-09 17:06:35 UTC
From: Henry Kolesnik <wd5jfr@oklahoma.net>
Message-ID: <usqg5083kosvb0@corp.supernews.com>
Source record: 40070

Looking thru the 1982 HP catalog I noticed that the HP 5342A was priced at $5500.00 and the HP 5340A was priced at $8600.00. A 1989 Tucker show the 5342A at $5675.00 and the 5340A at $7995.00 I'm not a counter expert but they're both 18mHz counters and the 5340 being older has nixie tubes. Why would anyone pay more for theolder technology, I know I must be missing something. What is it? I'm looking at up grading from a 5341A and wonder what the counter experts opinions are on the 5340A vs the 5342A.

And what about the blind box working with a PC , the 'Pegasus' ? Adds for
this unit disappeared in QST when the Jupiter was launched.
Apparently ,similar to the now 'deceased' Kachina ham transceiver , radio
amateurs don't want a box linked to their PC ,but a stand-alone unit.

3711. Not sure about antenna tuner

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-11-09 19:57:50 UTC
From: Dave <local_42@hotmail.com>
Message-ID: <2Ndz9.33061$Dc4.124412@rwcrnsc51.ops.asp.att.net>
Source record: 40074

After doing a quick search I'm still not sure if an antenna tuner is worthwhile for my set up. What good will it really do for my rig? If an antenna tuner might prove useful then that's what I'll whip up this week for the station. Here's the situation; Just put my antenna switch into my system and it has effected SWR by a bit. My dummy load used to read 1.1 or less and my vertical was reading about 1.2. Now with the switch inline I see 1.2 on the dummy and 1.5 on the antenna. I know 1.5 isn't bad but I'd like to squeeze every last bit of power from my little 4 watt CB. Will an antenna tuner help to cut down on the reflected power I'm now seeing or will it just show a nice match to my radio? When I start putting together my next antenna It would be nice to use a tuner inside the shack to fine tune the antenna as opposed to putting it up on the mast, checking SWR and bringing it down again until I get a decent match. I just don't understand if it really helps or just shows a nice match to the radio to prevent damage from a poor match. Any help is greatly appreciated. You guys have been great help with my last two questions and I look forward to any insight you can give. I've already located a couple plans for tuners I like just don't know if I should bother building it or not.

Thanks again,

Dave

Source record: 40076

All the tuner will do is show the radio a nice match - it can't change the antenna or feed line, etc. However, let us just examine the dreaded SWR issue a little more.....

Everything you put in line will lose a little power, and the difference between a 1.2:1 and 1.5:1 isn't really worth the trouble - at 1.2:1 you radiate around 99.2% or 3.97 Watts of your 4W, whereas 1.5:1 is around 97% or 3.88 Watts. The added 0.09W would make absolutely no difference at the other end, and you may just lose that amount from insertion loss anyway.

If you want to radiate as much power as possible then take the antenna switch out of line!!

3714. Re: Not sure about antenna tuner

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-11-09 20:53:18 UTC
From: "Bob Lewis (AA4PB)" <rlewis@staffnet.com>
Message-ID: <usqte1iccu0v43@corp.supernews.com>
Source record: 40077

The difference between 1.2:1 and 1.5:1 is so insignificant that there is no reason to even consider it. A tuner located near the transmitter will have no effect on the SWR in the feed line between the tuner and the antenna. It will only affect the SWR on the feed line between the tuner and the transmitter (i.e. it will make the transmitter see a lower SWR).

3715. Thanks for the input (was: Antenna Switch Questions)

Thanks for the input guys. I decided to just go with simple but effective and used two rotary switches to control two inputs to four outputs. I'll just have to remember to keep the rigs on different antennas or to switch one over when I want to transmit. Luckily when I forgot to do that on my first test run I was just using an old hand held that can't be putting out more than 1/2 a watt plugged into the switch, doesn't appear anything was damaged on the other rig. The project overall turned out nice. Looks good on the outside, my soldering could use a little more practice but that will come with time. The switch did cause my match to go from 1/1 for the dummy to 1.2/1 and 1.2/1 on the vertical to 1.5/1. Now I think I'll start work on a new antenna.

Depends how low - a small AM portable can do a pretty good job of DFing the AM broadcast band and the direction finding antennas for aircraft radio compasses operating between 200 and 530kHz can easily be held in one hand.

The HF DF used with much success in WWII against German U Boats were fitted to quite small warships without taking up much of the limited real estate.

Thanks guys. Seems I was right to question the need for a tuner. I never considered just how little a 1.2 or 1.5 SWR effects things. Instead of wasting time and money building a tuner I really don't need at the moment I can spend that time working on a new antenna. Just wish this blasted rain would quit so I can get out and try a few designs.

==========

Dave, you are thinking along the right lines. The purpose of a tuner is to ensure the transmitter sees its correct load impedance (usually 50 ohms). And nothing else. The transmitter then puts out the maximum safe power it is designed for.

Far and away the best place to locate the SWR meter is immediately alongside the transmitter. Permanently. Not only does it ensure the existence of 50 ohms exactly at the place it ought to be, it's convenient to see and adjust.

The tuner should then be in the feedline immediately next to the SWR meter.

When the meter indicates 1-to-1 then the transmitter does indeed see 50 ohms. In general, only when a tuner is used can the 50 ohms be set exactly regardless of what is done to the feedline and antenna.

So I suggest you invest in one. Better still build one yourself. Get it working and THEN think about what box to put it in. Strictly speaking it doesn't really need a box when it's indoors. Keep it compact, all the wires short, straight and bent at right-angles. It's satisfying to show the neat working components to curious visitors.

A tuner never loses its usefulness. If you should change transmitter, antenna, selector switches, or all three, the tuner will always be there to do its job - providing the correct load to the transmitter as indicated by the SWR meter.

By the way, forget about reflected power indications. What you read about on that subject in the magazines and especially on newsgroups is mostly confusing waffle which leads people astray.

Yours, Reg, G4FGQ.

3722. FS: 400 watt VHF/UHF Linear Amp..

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-11-10 00:21:00 UTC
From: ga_boneyard <ga_boneyard@hotmail.com>
Message-ID: <MDhz9.661835$vq2.4672033@news1.east.cox.net>
Source record: 40085
Cross-posted to: alt.ham-radio.marketplace,rec.radio.amateur.boatanchors,rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.swap

Put a big signal on 2M, 220 Mhz or 432 Mhz..

AM-6155/GRT-22 Linear power amp, 225-400MHz, 50W out (AM rating -- conservative) 10W in, Eimac X651Z/8930 final, extensive metering, rack mount 7" high, 80 lbs, ITT (model 3212), Part of AN/GRT-22. FAA Surplus. 110 VAC supply.

This Amp uses Emiac X651Z/8930 in silver-plated cavity-drawer; 175-turn TUNE counter dial. Main chassis has solid-state power supply and buffer amp/mulitplier; panel meter monitors voltages. Requires 105/120/210/240 VAC 50-400 Hz and +20 V req 60 ma. +20 V keyed; 7x19x18.5, 80 lbs shipping weight.

The HV Supply from AM-6155 is Loaded with GREAT parts to include a 1752V at 270ma transformer, 8HY 300ma choke, 100K ohm 95 watt resistor, 2x5mfd 3KVDC capacitor, & rectifier circuits card.

One ham has used a 4CX400A (available from Svetlana)to raise the output power to 450 Watts. Others have reported that you can run the 8930 (electrically identical to 4CX250R/7850W) at about 400 watts on 432 Mhz...

A quick Google search on "AM-6155" produced many hits of conversion information.. Check it out.

Used - Excellant Condition (NOT TESTED -- because it is not converted, yet!) $295.00 plus shipping from zip 31088.

Email if you have any questions.

73,

Larry Keith, KQ4BY

As W. Hill notes the 1943 first edition Radio Engineers' handbook by Frederick Emmons Terman is a classic and at a good price here too. If I didn't already have on I'd get it.

> was there, they had a separate Harris commercial amplifier for each band.

Equipment listed below, from the ARRL web site via Dino's earlier
posting. I wonder if they were phase-continuous from one key-down to
the next. If so, one could measure their freq pretty accurately, if
close enough to receive a really pure signal, and given a good enough
reference. Sure couldn't from where Roy and I live.

Cheers,
Tom

Equipment to be used for the 2002 W1AW Frequency Measuring Test

Transmitting Equipment:

* Harris RF-3200 Exciters w/ Harris RF-3220 Solid State Amplifiers

Antennas:

* 80-meter cage at 60 feet
* Phased 40-meter yagis; 65 feet and at 130 feet
* Phased 20-meter yagis; 35 feet and at 70 feet
* Phased 15-meter yagis; 45 feet and at 90 feet.

CW Generation:

* Compaq 133 with DRSI packet card (used to control matrix)
* ARRL Laboratory-designed Keying Matrix (keys all exciters
simultaneously)

Measuring Equipment:

* Hewlett Packard Z3801 GPS Receiver/Frequency Standard (provides
10 MHz
reference)
* Optoelectronics 8010 Frequency Counter w/ 10 MHz signal
reference
* (QST Product Review)
* Dunestar Bandpass filters
* Alpha/Delta switches

But, Reg,

Why would you even consider using a tuner on a CB installation when the VSWR is only 1.5:1??

I've got an IC-706IIG and it hears alot of RF but it can't resolve the audio from a signal very well at all unless its better than S6. I'm looking at the K2 because from the reports I've read it will give nice audio even from the weakest of signals.

I haven't purchased the kit yet because it takes alot of aussie dollars to buy a K2... (and even more hours being a social worker) but hopefully sometime next year I guess I'll build and will be able to suck it and see for myself.

The part you describe is powdered iron, not ferrite. Amidon's powdered iron parts came (and still come, as far as I know) from Micrometals. I don't know of anyone else who makes equivalents of Micrometals low-permeability parts. I suggest that you contact Micrometals, or check their web site, to find a UK distributor for their parts.

Fair-Rite makes ferrites, not powdered iron. I'd be amazed if Fair-Rite, an old and established company with a very large commercial customer base, was bought out by Amidon, started as a garage retail operation by Bill Amidon primarily to sell small quantities of Fair-Rite and Micrometals parts to amateurs. But stranger things have happened.

Speaking of good receivers, take a look at the CDG2000 project, at www.warc.org.uk

The architecture is very similar to the K2 - ham-band only and single conversion to 9MHz - but there are some significant refinements including G3SBI's H-mode FET mixer and VCO with very low phase noise. The resulting IP3 is around +40dBm (yes, plus forty!) and noise degradation is limited by other people's transmitted noise. In other words, the receiver front-end performance is no longer a limiting factor in what you can hear. This is probably *the* best amateur HB receiver front-end around today.

Parts of the transceiver are "standard", for example the highly respected Bill Carver IF strip (they developed a new PC board for it, which may be useful for other projects). Also the transmitter is pretty ordinary as yet... though in time that may change.

The big problem, of course, is that even when PC boards become available, it's is still a major HB project. You have to build your own case, and performance will depend on how successfully you shield some of the boards.

Also the control interface is under continuous development. It is based on i2c protocols, so it's very adaptable... but only if you have the programming skill. All the code is published, but if you want something different from what's already available, you have to either program it yourself or persuade the main software developer that your changes would be useful to a lot of other people.

Some examples of the CDG2000 have an extremely basic "programmer's" control interface which is not very practical on-air, while others are more operator-friendly but also require more controls, wiring and programming. DSP is coming... but that will require some further rebuilding as the DSP progressively replaces the existing hardware.

As with any HB project, the great dread is that by the time you've built it, the main thing you've gained is the knowledge of how to do it *properly* next time... which you simply cannot face!

Interestingly, the CDG developers say "If you want a transceiver that's darn good (through not quite as good as ours) because you mostly want to *use* it, then get a K2."

Source record: 40090

I'm trying to find an equivalent by another manufacturer to Amidon's T-50-12 or 17 mix. It must have a permeability of around 4.

I require a 1/2" torroid to use as an output transformer in a VHF RF amplifier stage.

I have looked at Fair-Rite products, who I believe are now owned by Amidon but have had no joy.

It seems Amidon do not have an official, or unofficial UK distributor.

I do not really wish to import from the US in relatively small quantity's if I can find the components here in the UK.

Any idea's?

Must be something wrong if you need an S6 signal to get any audio out.
What is the noise level at your location. Any receiver (including the
K2) is going to require that the signal is stronger than the noise to
copy it. If the 706 has an S5 noise level the K2 will likely also have
a similar noise level. Not bashing the K2, but I would be quite
surprised if it copied many signals well that you couldn't even hear
with a working 706. Where the K2 shines is in its ability to copy weak
signals in the presence of very strong signals.

That's why a good receiver like the K2 could indeed copy things you
couldn't hear on a 706.

To hear some "very strong signals", come listen to 7MHz in Europe after
dark.
Our band ends at 7.1MHz, and from there up it's solid with horrendously
strong short-skip AM broadcast signals. With a receiver that's prone to
intermodulation - like the IC-706 - the background from 7.0-7.1 becomes
a continuous mush of IMD at S7-8-9. Amateur signals need to be at least
that strong to be workable at all.

You can't tell that the IMD is composed of speech and/or music, because
there are so many different signals mixed together (many of them with
their modulation content frequency-doubled) and overlapping. It sounds
very much like "noise", until you have the experience to notice that it
doesn't flicker in quite the same way as either "smooth noise" or
overlapping static crashes.

With a good receiver, that intermod isn't there, or very rarely and only
in a few spots. Then you discover that the true background noise level
is much lower, so you can hear weak signals, and there are even empty
spaces between them. The first time you hear this is one of amateur
radio's genuine "Oh wow" revelations!

In other words, with a good receiver, 7MHz after dark sounds much more
like it does in the daytime... or perhaps most of the time in the USA.

Only ? Only 1.5:1 ?? You must be joking!

The SWR meter could be in error by 1.5 and the actual SWR could be 3:1.

I wouldn't want to push my luck that far and it would be an interesting project to make one.

And it's always useful. It can indicate which way to go when messing about with feedlines, line switches and antennas. Capable of providing a lot of operating satisfaction.

Have you no imagination ? ;o)

Reg.

I fully agree, however we don't know that his problem is front end overload. What I read into his post is that he can't copy any signals on any band unless they are at least an S6. If his problem is high ambient noise level (power lines, etc) then he may be real disappointed if he invests in a K2 and doesn't find any improvement in the local noise level.

Here on the east coast of the U.S., I don't find that I normally have to deal with very strong signals with my type of operating. Most of the QRM I experience is from stations operating close to my frequency. Things like passband tuning and notch filters do me the most good but these are things the K2 does not have. I had a K2 here (a field test unit). Based on several people who said they could often copy signals on their K2 that they couldn't even hear with the 756PRO, I did a number of A-B tests using my PRO. Never did I hear a signal with the K2 that I couldn't copy with the PRO (nor the other way around). Often however, I could make a signal more "comfortable" copy by using the QRM fighting features of the PRO.

The K2 is good but like every rig I've ever used, it has its "warts". Like all rigs, it does some things very well and others not so well.

In general, hams and CBers worry way too much about SWR. 50% reflected power does not mean that only half the power gets radiated by the antenna. The only thing SWR does is to subject the signal to the feed line loss more than once so it results in a little more feed line loss. If the line is fairly low loss to begin with than even a 3:1 SWR is insignificant provided that the transmitter will load into it okay.

Below 30 Mhz with a reasonable feed line, working to get a 1.5:1 SWR lower is a waste of time.

It's worse than a waste of time. Other than adjusting the antenna, anything
you do to "correct" the problem is going to introduce more loss than you
gain by getting to 1:1.

Hmm....in the old days (!) we used these to descramble Satellite TV...until the built-in memory cudn't handle all the keys anymore. I still have a HB programmer that takes COP cards, but I really dunno if I still have any data on its use...even have a couple of COP cards and maybe also a couple of COP ICs here :-) collecting dust. Problem with them was that the control program in the COP for descrambling was never released, as opposed to widespread PIC control program, so COP cards died long before they shud.

Tip: Check the newsgroups alt.satellite.tv and ....tv.crypt for info.
Besides all the whackos and the kids asking for new keys/management keys on these groups, there are a few cool guys that might help you out.

FWIW Cheers /Rick

3742. Brainstorming Designs for new 40 meter txcvr..

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-11-10 17:34:17 UTC
From: Jason <kc7eip_nospam@shaw.ca>
Message-ID: <tMwz9.775668$Ag2.26874233@news2.calgary.shaw.ca>
Source record: 40006

Well i am in the process of designing my own 40 meter txcvr.I'm along way from going to copper and solder, but I have a couple of ideas that i wanted to put out to the field. Here is what I'm wanting to accomplish,granted i know there are easier ways but here is what i was thinking on. I was wanting to use a combination of pics one as a freq counter that would feed the second the freq at specified intervals then the second could control the voltage to the varactor to adjust the freq up or down as needed..

I'm not quite sure how I'd use the pic to vary the voltage though either switching resisters or maybe use it to switch out caps directly instead of using a veractor...
Granted this all could be done using a lot les complicated using a POT and turning by hand and just using 1 pick to output the freq. and adjusting by hand.. the other way i thought is to use the second pic to run a motor that could actually turn a pot for me.. any way these were just some ideas i had on how to adjust frequency.

Yes, I sure have, Reg. There are times when a tuner is very useful but to reduce an SWR on a feed line from 1.5:1 to 1:1 is not one of them. Of course if he places the tuner at the transmitter then he hasn't done a thing to the SWR on the feed line. I'm not being discouraging, I'm just stating that to buy or build a tuner for the application he described is a waste of time and effort (unless of course you just want to build a tuner for the fun of it).

But then it would be a different problem. WWV and CHU provide steady
long duration carriers.

Did anyone here try it? I could only get a good signal on 80 meters.
I did get in several tries in the 15 minutes they were on, and my
readings were consistent to 0.5 Hz. Unfortunately, my measurement procedure
has some ambiguities and if I slipped in resolving them, I could be
off by tens of Hz. My report has been sent in.

3748. Commercial Kits for HF

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-11-10 19:21:36 UTC
From: Simon <st599@ecs.soton.ac.uk>
Message-ID: <92ctsusa4mtjt7ltmhnnlroqdp4tuf1b39@4ax.com>
Source record: 40011

Hi

I'm currently looking for a low power transceiver kit for operation in the HF Bands. The specs would be as follows:

Must be commercially available

RF output tuneable to 10W or less

Frequency display (preferrable)

SSB-AM and CW operation

Small portable preferable battery operated.

These limitations occur as I've currently only got time to study for an M3 licence, which prevents me from using a built from scratch transceiver.

Also which bands would peole recommend for a newbie.

Thanks

Simon

Hi Ian,

I recently received a mail from a belgian Ham living in DL. This guy gave me the URL of a very interesting variable condensators producer in Germany. All in kit and have very attractive prices, much lower than factory made. Seems of very good quality. Have a look. Here is the URL: http://www.schubert-gehaeuse.de/prod04.htm . Unfortunately the site is only in german but not to hard to understand.

>
>Fair-Rite makes ferrites, not powdered iron. I'd be amazed if Fair-Rite,
>an old and established company with a very large commercial customer
>base, was bought out by Amidon, started as a garage retail operation by
>Bill Amidon primarily to sell small quantities of Fair-Rite and
>Micrometals parts to amateurs. But stranger things have happened.

When Bill Amidon started his little business, both Micrometals
and Fair-Rite would sell their products in minimum quantities.
Micrometals had 100-piece minimums on direct orders; still did
until three months ago. Amidon would repackage into small
quantities for sale in electronics hobbyist stores and received
permission to reprint certain Micrometals Q curves and technical
information in those repackages. Very handy for hobbyists.

Bill Amidon retired in 1990 but his little business continues as
part of www.amidon-inductive.com and that company continues
with the radio hobbyist line. One can mail-order parts and
kit packs from them. Amidon-Inductive takes VISA or Master-
card. Their on-line order form indicates foreign (to USA) sales
are possible.

Micrometals specializes in powdered-iron core products. They
have a good website for technical information at www.micrometals.
com. They have two free DOS-based programs for power and RF
inductors, also a couple Application Notes on RF inductors. Their
whole catalog has been on CD since June but one can order parts
of their catalog. I recommend the Q-Curves section, 30 pages of
graphs. Good product line that has been valuable to me for over
two decades.

MY BAD!!!

Ten Tec currently offers both the Jupiter ($1189) and Pegasus ($895) HF transceivers. It is my understanding that a Jupiter is essentially a "Pegasus with a front panel". Both are currently on the TT webpage, and Jupiter was most recently advertised in QST in the September, 2002 issue.

Jupiter can be had with an internal ATU for $1488, too. I don't know about Pegasus and an internal ATU.

Sorry for the wrong info. I must have had a halfheimer moment!

Thanks for the heads-up, Danny.

I believe the 5340 had dual samplers and the 5342 had a
single sampler. The latter is obviously cheaper but
may not do as good a job of counting pulsed signals
like radar. It is also possible that the 5340 may be
more sensitive. Also, an interesting feature of the 5340 was
that it had a single connector that covered the whole
frequency range, rather than low frequency and microwave
inputs.

As a general rule, you shouldn't assume that newer counters
automatically have better performance than older ones.
The 5340, 5345, 5360, and 5370 were "cost is no object" doomsday
machines. At the time of their design, the HP Santa Clara
Division had a performance oriented general manager. Other newer counters
were designed under more business oriented general
managers.

(Note: I worked for the HP Santa Clara Division for 19 years).

Hands Electronics <http://www.rf-kits.demon.co.uk/> has quite a few nice kits. They are a tad pricey on this side of the pond, but over there they probably would look a bit more attractive. Also, the DL-QRP club <http://www.werdau.net/dl-qrp-ag/> has a Black Forest rig that is pretty close to what you describe which I believe they have a kit for. Again, it may look a little more attractive on that side of the Atlantic. Don't know if the QRP Club satisfies your need for "commercial", but Sheldon's rigs certainly should.

Others have mentioned the K2, which is an extraordinary radio. But by the time you get the SSB option and get it over there, pay the duty, etc. you are probably going to be in the 1500 Euro neighborhood, maybe more.

Sorry Bob... I am exaggerating a little bit... I hear weak signals but I am not happy with the tone of the radio, and weak cw get diffused with the background noise... even at low levels.... although with a bit of noise - say at S2 level will certainly run down an S6 signal very easily.

I had an IC756 a year or so ago and it had a reasonable rx'r. Sometimes when the band seemed quiet the scope would indicate a high floor noise. A techno guy explained to me that the quiet reciever was simply it being desensed by some other strong out of band signal.

In other words I wasn't hearing anything at all.

Quit possible. The atmospheric noise level can also vary considerably
from one moment to the next. If you've got front end overload going on
then the K2 will likely be an improvement. It should also help to
switch in an attenuator on the existing receiver provided that the
signal you are trying to hear is not so weak that you can't copy it
with the attenuator on.

Try a web search for 'Huff and Puff' stabiliser, some people have used PICs
for this. Or use a PLL synthesiser controlled by the PIC.

==========

People get their knickers in a twist about SWR. The amount of waffle it generates is right out of proportion to its importance. The so-called SWR meter does not measure it. Nobody has measured SWR since the thing was invented.

It attracts a great deal of attention because the nice looking meter is the only measuring instrument in the shack to be seen and read and talked about. It becomes an obsession.

What really matters is whether or not the transmitter sees 50 ohms. That's what antenna tuners are for.

But I admit SWR provides a nice excuse to have a friendly argument about it. ;o)

Problem: In connecting a keyer to a tcvr, I'm using a Radio Shack microphone cable product: 2C/24 Type LL2x. (I assume that it is two conductors, 24 gauge. And there is a braid shield.) At the keyer end there is an RCA plug; at the tcvr there is a phono plug. I feel the gauge is too large because at times there are intermittent shorts and I have to jiggle the wire to straighten it out. Is there a smaller gauge product I can use for this application?

Thanks,
Evan

How would one go about getting the RA to authorise use of a kit, I'm
not willing to stump up for the elecraft kit just because someone at
the RA says it's better.

If it's a matter of testing, I can do that myself using a spectrum
analyser or VNA to test the output frequencies and powers.

3781. More on HF DF (or ADF)

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-11-11 20:38:57 UTC
From: Jim Weir <jim@rst-engr.com>
Message-ID: <jc40tu0pn2qkeg6kvmi5rqlse8vs01s5ua@4ax.com>
Source record: 40043
Cross-posted to: rec.radio.amateur.homebrew,sci.electronics.design

There has been some discussion on this NG about how to detect the location of a transmitter in the HF region (80 and 40 meters is the subject of some interest here) using everything from a handheld radio's loopstick to a curtain array that will cover several dozen acres.

Suppose, just suppose I wanted to fix a small, lightweight antenna in a single position and in some way figure out the direction of a distant signal relative to some known horizontal axis of the antenna.

In the old days, we would have actually rotated a coil "loop antenna": relative to a fixed "sense antenna" and driven the motor on the coil to null the combined cardioid signal of sense added to loop. By measuring the motor's position and driving a meter in some sort of goniometer arrangement, we could then use the meter pointer to locate the signal relative to the coil's orientation.

When we did this arrangement, radio receivers were moosey things that glowed in the dark, and it was far easier to rotate a loop than do all that messy digital stuff with hot fets.

That is no longer true. A good receiver chip that will amplify and limit the signal, producing a digital output, is the size of your thumbnail or smaller. Digital power is a nickel a gigainstruction or thereabouts. At any rate, it seems to me that there is a better way to DF or ADF (direct bearing readout) on an HF signal than motors and rotating coils. Ferrites and toroid techniques are available that we didn't even dream of in the old days.

I've done a fairly exhaustive web search to see if this has been done before and have come up dry. However, my web search skills are not as honed as some in this group, I'm sure. Anybody got a pointer to a "how to" article on HF ADF using a small, fixed antenna?

It seems to me that nowadays, when we all can have nanosecond-accurate
gps-based synchonized clocks also synchronizing our receivers, it should
be possible to find the direction and distance of a transmitter without
any directional antenna.

With 3 or more distant receivers, correlating their reception, it should
be possible to pinpoint a transmitter within milliseconds. Is anybody
aware of amateur projects that uses this principle?

Hello,

Me,and some friends are active with direction finding stuff.We build a doppler with 4 antennas and it also works on 28 MHz (when mounted on the roof of a car).For lower frequencies is this not so good because the antenna's are too close to eachother.

But there is a system with 2 crossed loops and a sense antenna in the middle.You see (or saw) that on top of ships.You can detect the direction (not the distance)
A few weeks ago,I also wanted to know more about this,but didn't found anything on the web (except where to buy it).

So any tips about that system will be appreciated.

Bart

Having used one I have to agree. It is a reciprocal counter, meaning that it counts its' (500MHz) timebase using the input signal to gate the count, then calculates the frequency. Result, high resolution measurements dependent only on gate time, not input frequency.

BUT......

Repairing one is another matter. It is pre-micro, and it is packed with TTL chips that work like a big state machine. The only sane way to trouble shoot it is with the manual (of course) AND a logic analyser. (been there twice)

BTW, the "Rolls Royce" of the HP counters has to be the 5370. Like most high performance counters it used interpolation, but the 5370 did this digitally using a dual vernier method of interpolation that had a patented triggered phase-locked oscillator (using HP's 5GHz silicon-on saphire process)for the vernier that was self-calibrating. This gave an effective time base gating resolution of 100ps (equivalent to having a 10GHz timebase oscillator!). (Check out the August 1978 HP Journal for mor info)

They just don't make 'em like they used to :-(

Cheers
Steve Quigg.

Either I was not clear in the original request OR you intended to start another thread, which is OK also.

However, my intention is NOT to pinpoint a transmitter location using multiple receivers. The intention is simply a solid state A-DF without the use of rotating loops for a fixed location.

Try searching for hf+radio+foxhunting or something similar. I got over
1,700 hits with that one and with hf+radio+df it went up to 18,900.
Somewhere in there you will probably find some useful information.

I understand it is quite a popular hobby in Europe and seem to recall
having read a number of articles on HF DFing in various Ham
publications.

Was there ever an ARRL report on the 2N2/40? I would be real surprised. In fact, I'm sure I would have noticed since I built one.

You can read lots about it on http://www.qsl.net/k8iqy

also at http://www.fix.net/~jparker/norcal/2n2/2n2.htm

There is an outstanding QRPp article which, unfortunately, isn't available online, but there is enough information on k8iqy's site to build one. I would recommend ordering the QRPp reprint from Norcal though, it really is an outstanding article.

Precisely so. And if you estimate 2 minutes checking out each hit, in the first case you've slogged through 56 hours of time and in the second case you are up to 630 hours. What both I and the other gentleman who was looking for information were asking was if there were some other search criteria that might turn up what we were looking for in a bit less time.

Jim

A quick google shows the 6481 is equivalent to the CV5224 and RT434:

http://w1.871.telia.com/~u87127076/tabeller/cv2000.htm

Frank's electron Tube Data sheets has many listings at

http://www.mif.pg.gda.pl/homepages/frank/vs.html

The RT434 data sheet is at

http://www.mif.pg.gda.pl/homepages/frank/sheets/137/r/RT434.pdf

The heater is 6.3V @400ma.

A picture of the 6481 is at

http://www.tubecollector.org/6481.htm

That tube might be hard to find. Have you considered modifying the
oscillator to use a transistor?

The Philips PBR941 would handle the frequency but might be limited in
power output. Philips has other versions with higher current and
collector breakdown voltage. See

http://www.semiconductors.philips.com/selectionguides/tables/15613.html

Good Luck!

Mike

I'm fortunate to be a proud owner. Bought it new in the 80's and it still works great. One minor quibble - with interpolation, the single-shot time resolution is 20ps. With averaging, you can measure down to 100 femtoseconds. Here's a nice analysis of the performance:

http://www.febo.com/time-freq/5370B/

Jim, I know of a method called 'Time of Arrival' which requires some
physical space for the antennas, but it works on HF. Possibly adding that
to a search could be useful.

Interesting subject.... As far as I know, 'time of arrival' is the most
common technique but it DOES require three horizontally separate antennas
which need lots of room.

==========

I also suspect using several Quads, or similar directional antennas,
could be switched by solid state RF combining and such to simulate a
rotating antenna. Similar methods are used at VHF for doppler DF although
they use hard on/off switching. If you got the phasing right, and used
linear attenuating switching, you should get a lot closer to getting the
effect of rotation.

Interesting subject.... As far as I know, 'time of arrival' is the most
common technique but it DOES require three horizontally separate antennas
which need lots of room.

On my homepages, at http://w1.859.telia.com/~u85920178/ you will find several hundred projects, most of which have PCB foils and component overlays.

The project at http://w1.859.telia.com/~u85920178/power/vconv_01.htm can be used to generate just about any voltage from -90 to +90 and uses no transformers! It can only deliver a few milliamperes, depending upon the final output voltage needed. I have also shown one use, for replacing HT batteries in antique radios.

http://w1.859.telia.com/~u85920178/use/tubepsu.htm shows a technique using a transformer and can be used to give many watts. I use a similar circuit to run my oil-fired boiler during power cuts. The only difference is that I use an external oscillator since I needed somewhere near 50Hz.

Hope you find the info interesting. Took me hours to put the projects together!

http://w1.859.telia.com/~u85920178/use/tubepsu.htm is what you need. You find it on my homepages at http://w1.859.telia.com/~u85920178 It basically says that you can use transformers backwards and there I give two alternatives:

1. Two 250 - 12v transformers to give 250v isolated
2. One 250v - 12v in a transistor inverter cct.

Both will give you what you want.

Have fun - Harry

Jim, http://www.uspto.gov/ (US Patent Office) is a useful resource.
Enter "radio direction finder" or similar in the patent search section -
you'll need to download a suitable viewer if you don't already have one,
the FAQ tells how and what. US patent 4,302,759 and 4,368,470 are
examples similar to what you want, but there are many more. This
particular patent uses two orthogonal loops with a whip and some phase
detection stuff.

It never ceases to amaze me just what sort of obvious things can be
patented, along with their seemingly endless variations.

Cheers

Nice for VHF and UHF but not easily scaled to HF due to the long
wavelengths.

The closest would be the No Such Agency's "Elephant Cages" at Udorn
Thailand, Synop Turkey, etc etc. These were electrically steared arrays
that took up lots and lots of real estate. I am sure the user interface has
been modernized to a nice video display vs the old analog scopes.

If one could read the type numbers on the transistors it would be
possible to make an intelligent guess, but it looks more like a 20 Watt
amp than 100. HF certainly, and posssibly designed for Class A use with
those emitter Rs. I personally would not use an SMB at the 100 watt
level either, and can't imagine Collins doing so.

The working voltage of the transistors and the turns ratio of the output
transformer will give you more clues.

Ah the mining is going to be in Cornwall, which is 150 miles from me. I guess our local news is a bit too local!. It hasn't been on the national news either here.

Thanks for the info.

I don't see that too large a gauge would directly cause this problem.
(it might be an *indirect* source)

You do literally mean a short, the transmitter keying when you aren't
pressing the key, right?

It is almost certain that there is a visible short in one of the two
plugs. You should be able to see it by removing the plastic covers,
flexing the cable, and looking carefully.

(that said, I would not rule out a defect in the middle of the cable. I
once bought a 12v transformer from RS and found the primary open right
out of the box.....)

Doesn't Radio Shack sell a prefabricated cable with a RCA plug on one
end and a 1/4" phone plug on the other? (if they don't - I would still
be tempted to buy a prefab cable with a RCA on one end. Cut off
whatever's on the other end and solder on a phone plug. They've done at
least half the work<grin>!)

I consider these ecowackos terrorists. Remember those forest fires a few months back out west? Why was that? Because those green wackos wouldn't let anyone clean out the underbrush. And if ANY sort of clearing was to be done to help break up fires they took em to court.

Got no use for them at all.

How about the original Ryan Stormscope patent? It does pretty much
what you describe. Try searching the USPTO patent #4023408 and
following. There are many updates to that patent. I'm not certain
that Ryan's original ADF patent is on-line; but if it is, you should
see a reference to that technology as well...

> Can anyone on the group supply me with any RF plate choke manufacturers
> that are still in business?
>
> I believe R.S. Miller are no more.
=========
If you mean by ' RF Plate choke' a choke in the anode power supply of a valve type RF power amplifier , I thought that even for commercial equipment these can be readily made around a polystyrene /Delrin / ceramic former , eg with adequate inductance for the freq. range while checking for unwanted resonance over the operating range.
In the Nov 2002 issue of QST ,on page 71 there is a photograph of the 'innards' of a ACOM 1000 RF Power Amp.(1.8 -50 MHz) with 2 chokes clearly visible ,one for HF the other for VHF (50 MHz)
From the Product Review article ACOM International is labelled as US distributor ,although their web appears to be www.hfpower.com and the price referred to is that of the manufacturer .If the manufacturer they might buy the chokes somewhere , although I suspect they make these components themselves .

In the UK ,Mainline in Leicester (not their Surplus Department) is usually a good source for a large variety of RF components.

With my not-center-fed 550-foot "dipole", the SWR routinely runs above
10 on all HF bands, but since I use open-wire line, I removed the SWR
meter so the high SWR would quit bothering me!-)

I recently had a look at a commercial RDF antenna that was an
appropriate size to put on a small airplane, if you wanted. It
covered all of HF and some above. I'm quite sure it's available to
anyone who wants to pay for it, though I suppose most of the people
who buy them do so with taxpayer money. As I recall, the antenna
structure itself was described as "annular slot". I was surprised by
its accuracy, though didn't have a chance to test it with as many
"real" signals as I might have liked.

Cheers,
Tom

"Jim Pennell" <NoSpam@killspam.com>
shared these priceless pearls of wisdom:

-> Jim, I know of a method called 'Time of Arrival' which requires some
->physical space for the antennas, but it works on HF. Possibly adding that
->to a search could be useful.

Time of arrival techniques are useful where you have (a) a large amount of room
and (b) are operating at a single frequency or closely spaced frequencies or
have a chart of TDA versus frequency.

I'm looking at an antenna in a coffee cup that will work on both 40 and 80
meters without switching.

Jim

There must, of course, be some modulation that covers a broad enough spectrum that you have something to correlate.

For synchronization, who needs GPS? You can synchronize very accurately with a lot of other available signals. One example is broadcast television, which nicely transmits synchronization pulses and tone bursts. An ordinary television receiver locks to the color sync tone burst within a very few degrees...probably within a nanosecond or so. I'm under the impression that you have to get fairly fancy with GPS to get that good...we've been doing some GPS-synchronized acquisition using internet-controlled "receivers," and my understanding is that you don't get much better than 50 nanosecond relative sync stability. That's not bad, of course...that's only 50 feet of propagation distance. There's also a patented technique for getting withing a couple hundred nanoseconds, just using internet connections (and hardware that reads special packets). In any such system, of course, you should expect to calibrate out systematic errors.

Several years ago, I thought about how simply you might be able to make such a system. You'd like to make receivers which have very little drift of their delay times. I wondered how well you could do with something like a "direct conversion" I and Q receiver, digitizing the outputs and feeding them to a DSP. Put emphasis on a high TOI, so you can leave the bandwidth wide, so you don't have to have filters with narrow bandwidth and long delays that can drift around. As with lots of other ideas, I never found time to develop that one. Sigh. The "receivers" in the system I mentioned above have a 10MHz bandwidth, and have the luxury of residing in temperature-controlled environments, so phase (time) shifts aren't much of a problem. Of course, you have to be careful with your synchronization signal also.

Cheers,
Tom

Do a web search on 'StormScope'.

This detects and displayse the bearing and location of lightening discharges, and I believe works on 100 kHz. The same idea would probably work on any frequency and signal type.

If I recall, it uses two loop antennas and a sense antenna. Very compact, as it is typically mounted on aircraft. I don't know what they are doing now, but in the original design the loops were wound around a square chunk of ferrite.

Bearing is based on the relative amplitude in the two loops, with the sense antenna resolving the 180 degree ambiguity. The distance requires knowledge of the strength of the 'transmitter'. For the StormScope, it turns out that all lightening bolts average out to some mean value, 20000 amps, I believe.

Goodrich Aerospace is currently the maker of the StormScope. I think they have one model for fixed use.

I'll have to disagree with you there.

30 years ago when I was 16 and still wet behind the ears with regards
radio I dabbled with 807's on the AM broadcast band.

Now with a 1/4 wave inverted L plus waterpipe ground it comfortably hit
the 25 mile marker.

Late one night a local ham turned up on my doorstep (read that as 1am in
the morning). I had a cardiac when he asked if he could come in for a
cup of tea.

To cut a long story short he had a Perdio Marco Polo receiver, a 6 foot
vertical whip used as a sense antenna and a horizontally mounted ferrite
rod clipped to the car roof above the drivers door. All this equipment
went through some kind of phase comparator or whatever it was. He was
able to track stations single handed on any frequency from LF through HF
while on the move.

If this fella could do this in the 70's I'm damn sure you could put
something similar together now.

You're right. I think I was getting confused with the 5360. When I checked the
article I quoted I see the following. Time Base clock is 200MHz (5ns period).
Vernier interpolates by factor of 256; -----> (5ns)/256 = 20 ps (approx).
Sorry for the mistake.
Cheers,
Steve Quigg.

Oops, more info. I just noticed that you are in the UK. I had no idea
that the military CV numbering was still being used into the solid state
era, but I think thats what you have on hand.
I found the CV7262...its a 1S5051RA zener diode, 51 volt, 10 watts.
I think these people could identify the other one...

You will need an ACCURATE Local Oscillator to feed the Mixer LO port.
(The LO will need to change for each band.)
The sum and difference between the LO and the signal is what will appear on
the IF port.
You then need to filter out the SUM and amplify the difference to feed your
scope.

Read about how receivers work, you learn while reading, and you will be able
to ask
better questions.

Many PIC's have an anlogue output too. Or you could use a basic A-D
converter chip.

OR

Many "computer control of analogue fuctions" are done by varying the pulse
width of a square wave output. You could do this easily in software, and
just use the output to charge a capacitor through a resistor. The cap would
charge to a voltage proportional to the duty cycle of the output waveform.
This is how the "digital control" of the really analogue control functions
(height, width etc) in CRT based computer monitors is done. All the control
is done by a single microcontroller IC with many variable pulse width
outputs providing the necessary reference voltages for good display.

Hi Simon

I am afraid it is up to the manufacturers generally to apply for type approval - a costly business, so costly as to make it prohibitive for the individual. It has to be carried out by an "approved body" too, of which there are not many. The fees these places charge for the work would make your eyes water.

I think it was a mistake to make no provision for say a "qualified person" to certificate kits built as OK and go down the type-approval route, but who cares what I (and many other non-RSGB members) think?

I've been working along similar lines for a little bit now, and it's not really quite the same thing as a huff 'n puff stabilizer. Obviously, you need some sort of a DAC, but if you do the math, the DAC needs to be a pretty pricey one, 14 or 16 bits. I don't think it would be realistic to get that sort of resolution with duty cycle modulation, but maybe.

What's really ugly is that serial 16 bit DACs in DIP packages are pretty scarce. An LTC1655 will do the trick but they are expensive. A DAC8501 is a little cheaper but I've only found those in a TSSOP which is a bear to solder.

I noticed a big, honkin' power supply being thrown away at work the other day, and I rolled it into a corner in case I decide to use it for a project. It puts out 90V DC and 25 amps. The regulator apparently is constant-current, and I don't know the circuit, so it might be difficult to convert it to constant voltage. If I can, though, this monster just might be able to power a sizeable HF amp.

I've scanned the 'net for solid-state amps, and haven't found anything operating anywhere near this voltage range. Can anyone (a) suggest a source for solid-state HF amp schematics that might match my idea, or (2) tell me why it won't work in the first place?

I've been out of homebrewing for quite a few years, and don't have all that much RF-homebrewing experience in the first place.

A similar thing has happened here in Canada. When there was
a licensing restructuring back about 1990, suddenly the entry level
license did not allow for building transmitters. The wording of
the material for the public (if not the actual regulations) seems
to sidestep the issue by talking about how the license allows one
to build receivers and accessories, as if you needed a license
for that.

While I admit most wouldn't be interested in building, by changing
the rules to forbid transmitter building it got rid of what I
consider a basic part of amateur radio. Up till then, one could
build at least a very simple transmitter, and get some sort of
results, but now you can't do that unless you pass the advanced
test.

While I've seen speculation about what constitutes "commercially
made equipment", I've yet to see a real definition of what
the rule is supposed to mean.

No, it's a followup question from about a week ago, when the poster
wanted to use his oscilliscope for measuring something at frequencies
beyond the limits of his scope. Someone suggested using a mixer,
and now he's back trying to get details.

If I remember the original question properly, he's not trying to
see a waveform, just wanting to measure the output voltage. If that's
the case, there isn't much point in using the scope, especially if
one has to build a converter to extend the scope's range. Better to
build some sort of RF voltmeter (or just a probe to work with an
existing meter).

Thomas,
he has done the most important thing, and that is to ask questions,
which is a very nice place to start. He has shown a willingness to
learn by asking questions. Perhaps you could recommend a easily
available textbook that his library might have to point in the right
direction. I dont think he can homebrew a spectrum analyser, and as a
previous poster mentioned probably a RF voltmeter would be more
appropriate at this point in his learning curve.

Unfortunately, and this is just a gut reaction, your posting reminds
me of years ago in our radio club - a novice would ask a question,
and immediately be put down by the "experts" - some of them never
came back because of this. Fortunately this has changed, and while the
newbies still ask questions about radio we try to answer them, in
return we learn from them as their confidence in the group grows - it
may not be about radio, we have competant machinists, cabinet makers,
people who grow champion roses and orchids, a myriad of skills, in
short all those interesting things outside my own narrow speciality.

Regards,
Andrew VK3BFA

See my other post on this.

The StormScope is now manufactured by Goodrich Aerospace (or is it
Goodrich Avionics?).

The basic idea for this has been around for decades, even before Paul
Ryan invented the StormScope. I remember seeing the basic idea in a
late 1940's vintage radio engineering handbook.

Just using the mixer and a signal generator for the local oscillator
will do the job. Yes you will
get the sum and difference out but who cares.

If wanting to look at 144 to 154 mhz, the signal generator would need
to be around 144 mhz.
The difference will be 0 to 10 mhz out of the mixer. The sum will
be288 mhz. The 10 mhz
scope will see the 0 to 10 mhz and ignore the 288 mhz.

With a 144 mhz oscillator signal you will also be able to see from 144
mhz down to 134 mhz.
Which is the sum and difference of the signal generator and the scope
band pass.

You need a fairly strong output from the signal generator if you want
good sensitivity from the

mixer. But even at lower signal generator levels you will get usable sensitivity for the scope. The
spec sheet from the mixer will give you values of how much loss you will have at different local
oscillator levels (signal generator levels)

Hi Guys,

I am looking for an article in Ham Radio Magazine, March 1968.
The article is "Modifing the Yaesu FT-310 for 30 Meters"
I would be interested in the issue or a copy of the article.

Thank you very much,

WA4MNT

3856. Operating desk on CQ cover years ago - looking for

Years ago there was a 7 land that had a really really nice 3 piece operating desk that angled on the cover of CQ and an article to build the desk inside.

Does anyone remember who the 7 land was and the article. Id like to build something similar.

Scotty N7HJ

Of course you need to 'scrounge' it. Thats a requirement to being a 'real ham'.

If you can't use it in ten years, trade it for some other 'scrounged' junque.

Hi Frank,

>In the UK ,Mainline in Leicester (not their Surplus Department) is usually
>a good source for a large variety of RF components.

My requirement is for a plate choke.

I shall contact Mainline.

Shame they have not produced a catalogue for some years. They only print
their surplus flyer.

Another gentleman kindly pointed out that Miller's do still exist. I
have requested a catalogue.

I do not wish to produce my own chokes as this is for a limited
production run product. I just do not have the time.

Thank you.

You could also use an op amp integrator that you
step up and down with pulses from the microprocessor.

I've seen this done with a small DC motor providing the
pulses - rotate one way for positive pulses, the other
way for negative pulses. The reference is at home, but
I remember seeing this in VHF Communications not that
long ago...

"DIP package"? What's that? :-)

Bob

The reason you don't see a lot of projects for that voltage isn't that common components don't work well there, it's that getting that voltage at any sort of current is a pain. The 12 volt nominal station supply is a big pain when trying to build and amp with some power. You end up needing horrid currents, and use transistors that are a lot more expensive than you really need.

Power MOSFETS in the 20-30 amp range at 150 volts or so that will work through the HF range are pretty widely available and cheap. It's a little harder, though, to find transistors that will do both at the same time (i.e. dissipate a KW or so) but they are available and they really aren't all that expensive, typically. It gets quite a bit uglier if you are looking for VHF, however.

The main problem is that you will likely need to do the design yourself. One huge advantage is that we are typically talking a few dollars for this sort of transistor. If, in your experimentation, you toast a few, it's a whole bunch different than toasting, say, a 4CX1000A.

And although 90 volts is a lot more friendly than the thousands you might need for a valve circuit, 25 amps can be pretty impressive so you do need to give it quite a bit of respect.

Sounds like you got the beginnings of a fun project!

..

The problem I see with this sort of approach is getting the resolution. Presuming you want to cover 100 KHz of 40 with a resolution of, say, 10 Hz, you need at least 14 bits of resolution, preferably a lot better if you are going to control it with any degree of success. That seems like a lot to ask from this technique.

> "DIP package"? What's that? :-)

Well, maybe you got smaller fingers than some of us <g> I suppose we're all going to have to learn pretty soon, tho.

yes, it works for lower voltages, believe it is not so critical. and the xtal frequency is not critical at all, you just use an odd xtal. A 26.985 xtal in 9MHz osc and multiplied by 16 for 2m, or you could use something around 48MHz and multiply by 3.
Sometime wondered if a diplexer was needed at the output, but used only an attenuator/termination. Not certain if LO needs good filtering, neither

From: Dave Bullock <DaveB@ihr.mrc.ac.uk>
Message-ID: <3DD354E6.6080308@ihr.mrc.ac.uk>
Source record: 39934

Homebrewers, here's a good question.....

The FT-101 "probably the most modified Ham bands radio ever"
or so the saying goes.
The 6JS6C probably the most sought after tube for this radio!
I have seen lots of modification info to convert to 6146B's etc,
but I would have thought that another of the radio classics..... the
4CX150 or (250) would have been a more suitabe choice.

Readily available, (10-a-penny) at junk sales, (even ones that are tired
of UHF would probably work on DC ...sorry HF)!
Unbreakable, (in this application) only being asked to produce 100W they
can dissipate 250W on the anode alone!
Removing all thet parallel wiring would probably remove the need for
neutralisation too!

As the newbie owner of an FT-101 in need of O/P bottles, do any of you
know what is the problem, converting the set to a single 4CX250?
(There must be something I missed)!

Please help.........

Thanks ...Dave

If you have the attenuator, and it looks like 50 ohms to the mixer, you
don't really need the diplexer, as the mixer will be properly terminated.

Indeed! Thanks very much for your posting. I'll check into higher-voltage MOSFETs. After I learn something about how they work (they didn't exist when I learned my basic electronics AFAIK). My suspicion is that I'll be able to adapt some existing circuits to the higher voltage and alternative MOSFETs with some work. And no need to run up into VHF - I can get by barefoot there. It's HF I want.

=====
Never having used such a valve (tube) myself ,but looking at one from the junk box ; fitting one inside an existing FT-101 means you'll have to devise a special air cooling system for this transceiver. I believe the 4CX250 is to be cooled with air of a significant pressure from below ,so when used in a chassis that chassis would have to be pressurised by means of a centrifugal blower producing a minimum pressure of 'X' mm water column ('X' probably found in the valve's spec. sheet).
Upon blower failure ,a pressure switch would have to switch off HT from the valve.

BTW ,depending on air pressure required ,a suitable pressure switch might be an adjustable water level switch from a domestic (laundry) washing machine.

If you're using the FT101 power supply, you're missing another 1000V on the anode. A 4CX250 will hardly do anything with 800V on the anode, and I wouldn't like to guess what suitable grid and screen voltages would be.

Then there's the whole issue of the special socket and air cooling that Frank mentioned.

I've just been reviving a 101ZD (last of the 101 line, uses 6146s) and was pleasantly reminded what a nice rig it is.

> 40 meters.
> Thanks in advance
> 73 Fred
> wb6iiq

Depends on what the choke is used for. If its reactance will be tuned
out anyway (as a plate choke for an amplifier with a pi output
network), it only needs to be a reactance around the value of the
plate load...which should make it several times the reactance of the
pi network's inductor...or it could even be less than that, so long as
it has reasonable Q (reasonably low loss). Avoid chokes with
self-resonant frequencies below your operating frequency. So about
100uH, which is about 4400 ohms at 7MHz, should be reasonable. I
guess a couple inches of close-wound #30AWG enameled wire on a
half-inch diameter form should do the trick. I believe its self
resonance will be up around 15 meters, maybe a bit below.

But if it's a filament/cathode choke for a grounded grid amp, you'll
need to use heavier wire, and because of the low impedance at that
point, you can use less inductance...so, it depends on what it is
you're choking. The exact value should not be critical, but getting
it in the right ballpark is.

Cheers,
Tom

>converter chip.

I would agree that a D-to-A PIC version could control a varactor which would control a VFO.

On the other hand, trying to do so even with the most-stable D-A output possible would not achieve good frequency control. The varactor/variable-capacitance-diode would not be stable enough to hold frequency to better than a few hundred Hertz at room temperature. To handle RF frequency stability requires something like a PLL or DDS, either of which could be driven by the digital output of a PIC, the PIC calculating the digital word necessary for the particular PLL divider or DDS register. That calculation could accept up-down pulses from a shaft encoder and also do calculation to drive any matrix display for frequency.

>This is how the "digital control" of the really analogue control functions
>(height, width etc) in CRT based computer monitors is done. All the control
>is done by a single microcontroller IC with many variable pulse width
>outputs providing the necessary reference voltages for good display.

Agreed. The advantage of one microcontroller for a number of front
panel functions driving voltage-controlled circuitry is more to reduce
the mechanical couplings and physical restraints of control
placements in manufactured radios. Microcontrollers are the
perfect choice for digital functions such as displays or digital states
for PLLs and DDSs. But, for homebrewing, things like RF gain or
AF gain can be handled with conventional wired circuits used years
ago.

Microcontroller use needs to take into account the harmonic content
of fast leading and trailing edges of digital waveforms and their
possible leakage into a receiver. The amount of design time spent on
free PIC development programs for a particular application may
exceed the total design-build time of more conventional analog
circuitry. This is especially true for those with little or no experience
in assembler programming. That has to be factored into homebrew
project decisions.

On the other hand, programming has its own unique "fun" and
guarantees an absolute control of desired functions...if the program
statements are written correctly. Such programs can be modified
on the computer quickly, proven in simulation, then applied directly
to a microcontroller through a burn-in accessory. No soldering
involved.

For those working with SMT, a suggestion:

Headband magnifiers are available in Arts and Crafts stores at less
cost than from electronics parts distributors. In the USA such a
chain is Michael's. I borrow my wife's headband magnifier from time
to time for close-up work...for many applications it is better than
a big lens magnifier with light on a stand.

I would change the word "possible" to "probable" in the above sentence. This problem shows up even in expensive commercial gear. Best approach seems to be to put the processor functions "in a can" and connect via feedthrough capacitors. This also keeps the processor noise out of other nearby equipment. It is also possible to do the reverse, but as soon as you connect an antenna you are back where you started.

The December 1975 issue of Ham Radio Magazine has an amplifier using a
single 4X150 in which both grids are grounded and drive is applied to
the cathode. It is billed as a linear amplifier for QRP SSB rigs. With
a driving power of 5 watts the output is 50 watts. There is NO forced
air cooling.

Hello, I'm taking an antenna theory and design class right now. I would like to find a good antenna book that I can use for practice problems. The textbook used in the class is "Antenna Theory and Design" by Stutzman and Thiele.

The book has the equations but not enough examples. I need a book with worked out problems.

The topics include:
antenna arrays, pattern multiplication,
resonant antennas (dipoles, Yagi-Uda, large loop antennas),
broadband antennas(helical, spiral, log periodic),
aperture antennas(horn and parabolic antennas).

Remember that this is an academic course, so many other types of topics, while interesting and useful will not be in the course. Can anyone recommend any good antenna books with solved problems on these topics?

I agree...but some have gotten away without full metal jackets.

An example is the old ICom IC-R70 0 to 30 MHz communications receiver. The internal microprocessor and ancilliary ICs are out in the open to some extent, but on a separate PCB assembly from the RF and front IF assembly. Of course, the chassis is an aluminum casting and it is well covered on all sides with near-zero holes/perforations. I have one and have never detected any digital noise from its innards.

One way to minimize digital noise is to use low-power CMOS wherever possible in the digital part of the receiver...and, of course, to bypass the #$%^!!! out of supply rails, use ferrite or iron powder beads in series with supply rail leads. Go for filtering overkill. There's no good way to predict the digital noise path to the input, but home-brewed designs allow that luxury...no manufacturing cost budgets for a few thousand units' production run. :-)

Prototyping digital circuit assemblies and trying some "sniffing" with an all-band comm receiver and a small probe loop will help to find out if the digital noise is low enough...before building it into a final design. If worst comes to worst, air duct galvanized sheet metal is fairly cheap and can be soldered with those big old irons gathering dust after the coming of the SMDs.

Is there any reason you wouldn't use a frequency synthesizer to do
this? It seems that with Analog Devices and National Semiconductor
parts, you could build a 40 Meter synth very simply.

Dave

Bob,

According to the "CV Register of Electronic Valves" CV7160 is equivalent to
VR575B and is a Zener diode. CV7262 is equivalent to IS5051RA and/or
IS6051RA and is a "Zener regulator diode". Hope that helps.

For more than forty years, I never thought a kit, especially one that cost far less than a kilo-buck, would or could outpace the receiver performance of the top of the line gear from the commerical manufacturers. Then came Elecraft's K2.

From formal product reviews that include instrumentation based assessments to the personal experience reviews and comparisons found at

http://www.eham.net/reviews/products/14

Elecraft's continued success is now way beyond cult following.

With > 3,000 K2 kits sold, the K2 experience (building and operating)
is one not to miss.

What will Elecraft do next to top the K2?

Source record: 39855

So far, all I have is the receiver board receiving cell base
transmitters, and I beleive I have the PLL properly working.

Next in line will be to make a transmitter (from another receiver
LO/PLL),
and set up a micro board to adjust the PLL (I am currently using a PC
to control the RX board).

On the RX board, I plan on somehow converting the signal coming into
the 1st IF filter down approximately 35 Mhz.

I am primarily experimenting with Uniden phones, whose RX LO is 45 Mhz
above the RX RF, and the PLL chips are Fujitsu MB87001, wth MB 501
modulus prescalers, set to 30 KHz channeling. Also in my bag of tricks
is an NEC phone (Whose RX LO is something like 94.5 Mhz below RX
RF,and uses an unidentifiable NEC PLL),
and a Nokia, which I am not too sure about.

Yes, theoretically. But with an old oscilloscope - as for newer, the
sensitivity isn't too high and you most probably will need a
'broadband post-amplifier' - 15dB 10MHz bandwidth is quite easily
achieved with a BFR90 or 2N3866 stage

The problem with PLLs is that the good ones, the ones Dave suggests, are expensive and come in these tiny packages that are very difficult to solder. I guess you can get "samples" from Analog Devices, but that seems a little dishonest to me. The less expensive ones tend to not have enough resolution or work at frequencies that are just too low to be useful.

Texas Instruments does have a "transmitter" chip that is pretty interesting. Basically it's a fairly complete high level VFO. There are 400 and 900 MHz versions and it's around five bucks. Gigahertz prescalers to bring it down to HF are only a couple of bucks. It, too, however, is in a TSSOP package with lots of legs, so you will need to make a high quality PC board and then solder the itty bitty legs. The soldering is possible, but you're not going to make that PC board with a Sharpie marker, so that process is going to drive up the price and difficulty.

You will find that it will be hard to get below the price point of kits like the Small Wonder Labs SW-40+ unless you have a really good junk box or go really low tech. Chances are you will need to collect parts from several suppliers, and just the postage will start to add up pretty significantly.

You can get pretty cheap if you go with a bare-bones, DC rig, but it's not going to have anything like the features you want.

You might take a peek at Jim Kortge's 2N2/40 for ideas. Won't help you with the PIC driven VFO, but the rest of it is there and pretty nice quality.

Yes i have had my hand at low tech :).. and thought that i might try my hand at a computer controlled rig.. Well pic controlled any way.. my soldering is good but I'm not that good :).. small smt is ok but much past 8 pins and I'm sure to make a bridge :).. I have taken a look at the swl rigs and some of the other ones and they are affordably in my price range but I was trying for something i could call my own... That being said. I think i will stick to low tech or semi low-tech and just ad a few ic's in the mix... a freq counter and keyer... and maybe a nice mixer in there as well i have played around with one and i like the gain although it's a little much for my little audio amp but i since fixed that ... but for now i think I'll stick to the simple stuff and add in the more hi-tech things when i have a better grasp and bigger budget... So after i have my VFO built I'll be back for more advice...

Can you use a op-amp as a preamp in a radio? I know you can use the 741 as a preamp on a microphone, but it's to narrow a bandwith for a radio.

Bill, N5NOB

I use one as an "EQ", while a 2N3904 does the preamp.
Stop in on my web site to see it, look for the "ICOM mic preamp" link.

Jameco still offers the Motorola MC145151P parallel-input divider
control in a 28-pin "standard" DIP pin spacing. $5.95 ea. singles.
It can be the VFO if you don't mind fixed increments of frequency
at 40m. Everything for the PLL is on-chip except the reference
oscillator crystal and the voltage-controlled oscillator. Jameco
even has the Motorola datasheet available for free download.

Jameco also has the Motorola MC1350P wideband amplifier
block for $1.19 ea. in singles, $1.09 ea. in tens. This is a
push-pull input, push-pull output amplifier which can be
single-ended at either end. It has DC control of gain and works
beyond 40 MHz (I've used it to 65 MHz). Can be a good IC gain
block for any receiver stage, even as a balanced mixer (LO into
gain control line). 8-pin DIP. Motorola datasheet on-line at
Jameco for free download.

If you want incremental frequency resolution better than a
recommended 1 KHz spacing, you can set the PLL at a
slightly lower frequency, say 6.0 to 6.3 MHz in 10 KHz
increments, and mix it with an analog VFO of 1.0 to 1.01 MHz...
an MC1350 as the mixer, perhaps another MC1350 as the
variable oscillator. The reason for having the VFO at a lower
frequency is better stability.

In going to direct-conversion, it might be better to add an "RF
stage" in front of the receiver section mixer to improve the
signal-to-noise ratio...every mixer has conversion loss and that
will degrade the ultimate S/N ratio. An MC1350 would work
there and also yield a stage that can be DC (voltage) controlled
for RF gain. A direct-conversion receiver for 40m would not
require any manual tuning since its maximum bandwidth is only
0.3 / 7.148 = 4.2%...or Q needed is only 23.8...two tuned
circuits (antenna input, RF amp to mixer input) could use a

staggered-pair tuned arrangement. MC1350 input impedance
is equal to a 5 K resistance in parallel with about 2 pFd of
capacitance.

Just some suggestions...

I am not sure whether you are asking about an audio pre-amp or an RF
preamp.

We live in neat times. There are some really fast op-amps these days.
TI just announced some voltage feedback amps (the op-amp type that most
of us are used to) that have up to 2000 MHz of gain-bandwidth. This is
100x gain at 20 MHz, 200x gain at 10 MHz, etc.

The noise level on some of these can be reasonable, but not ultra low
noise. I think the TI parts are something like just under 4 nV/SqrtHz.
Compared to 50 ohm noise of 0.9 nV/SqrtHz, it might give a noise figure
of 14 db or so.

These are certainly useful for increasing the signal level in a
transmitter, or perhaps as an IF amp in a receiver, but not so great as
a front end (RF preamp) to an HF receiver. It would boost the signal,
but not improve sensitivity, and would simply increase overload in the
receiver.

Normal op-amps such as a 741 have gain bandwidths in the 1 to 4 MHz
range and are not useful at RF frequencies. As an audio preamp, a 741
can be used as long as the gain is kept below 20 db or so.

I've built DC receivers without an RF stage (using a diode ring mixer) and found the noise figure to be entirely adequate up to about 20 meters. On 15 meters and above, an RF stage would be a good idea. The MC1350 is a very noisy amplifier, so I wouldn't recommend using it as an RF stage. Or as an IF stage unless you have a fair amount of low noise gain ahead of it.

If you're interested in looking at DC receivers, you might check out "An Optimized QRP Transceiver" in August 1980 QST, "The 'Ugly Weekender'" in August 1981 QST, and the several articles by Rick Campbell in QST since then describing his DC phasing rigs.

>
>Bill, N5NOB

If you are talking about an RF amplifier at MF and up, a 741 is
not good...its unity open-loop gain is around 2 to 5 MHz.

As I suggested to Jason over in the "brainstorming 40m rig" thread,
a Motorola MC1350P is still available from Jameco ($1.19 singles,
$1.09 tens, $0.99 hundreds), including a free-download Motorola
datasheet. It never had the greatest S/N ratio in the world but it is
low enough for HF front-end applications meeting a 0.3 uV
sensitivity criteria. It has a bandwidth in excess of 40 MHz and it
can yield 30 db gain no sweat. It can also yield 30 db of gain
control attenuation with a DC voltage on a separate pin. Not only
that, the 8-pin DIP handles as easily as any 741 in an 8-pin DIP.
Differential or single-ended input or output...your choice.

www.jameco.com [not an endorsement]

I have built a few air variable caps using aluminum sheet, phenolic or
(garolite) as the end plates and using stove bolts with washers as
spacers to hold the stator and endplates together, I assemble the
rotor plates and shaft from 1/4 threaded rod using washers as spacers
and nuts to hold the assembly together. On the back of the rotor unit
I use a small piece of sring steel bolted to the back plate and
bearing down on the back end of the rotor shaft to keep the rotor from
turning to freely though being connected to a vernier tuning knob this
does not seem to be much of an issue. basically copying the design of
air variables in possesion but being fabricated myself they are
wonderful additions to a receiver. I also make fixed capacitors like
the old micadon 601s and have made a few paper caps which perform well
in my grid leak and regen radios.....

My technique may not be what you are looking for but I thought I would
just throw this out there for you.
I had to turn to this method as I like building from scratch and being
as I build shortwave receivers and need small value air variables,
cheaply, and without butchering up a manufactured cap it has workd
fine.

I also have done vernier arrangements using friction drive and have
done a few vernier arrangements using plastic circles cut out of
phenolic and large rubber bands, they may look gruesome but they work

pretty well.

I really enjoy building my components, I hope to one day be able to fabricate my own triode and receive with it. I know of home built tubes but dont know how well they work in radio work, just something to waste winter time on....

Hope I didnt go too far off topic, I just love my raidios and dont often get the chance to talk about my work........

I know of no list. But months ago, I discovered that the US Patent Office has a website, and apparently ALL US patents are viewable online. I've looked up Armstrong's patents, and that was pretty neat. However, I've only looked at patents that I have numbers for. When I first learned of the site, I entered somebody's name (to find what might be the first product detector patent, actually for Jan-Martin who was looking at the time), and when I tried the search engine, I think both trying on name and "product detector" I got no results. I've never gotten back to trying the search engine, but it's there for all to see and try: http://www.uspto.gov/patft

From time to time, we've talked about QST and QEX on CDROM here, and sometimes people have wished for the ARRL Handbooks on CDROM. What I'd like is for someone at the ARRL to go through the archives and put together collections of related articles on CDROM. Since they've got the rights to the old Ham Radio magazine, they'd have access to a good portion of the ham technical articles over the years. There are some classic receiver articles (Armstrong must have had at least some articles about his receivers, Lamb writing about "single signal selectivity" in the thirties, that 1963 article about the 7360 in receiving applications and William Sabin's 1970 article about receiver design come immediately to mind) which would be nice to be collected together. The ARRL used to do this with specialized topics (VHF, SSB, mobile, etc) in book form, though in recent years the compilations seem focused on QRP. Since the articles are already in electronic format, the main deal would be selection, and the whole project could even be a "publish on demand", ie write a CDROM when an order comes in. If they could throw inpertinent patents, that would help fill out the material.

Download program TRIODE1 from website below for full analysis/design of Class A,B,C power amps, grounded cathode. (Unsuitable for grounded grid). Design includes output tank and Pi-match.

An example design, built into the program, is based on a 3-500Z. Hit one key and you have it all. Ready for changing operating angle, HT, bias conditions, etc.

Grid driving impedance is one of the computed circuit parameters.

A neutralising circuit is not included in the analysis. You will have to sort that out for yourself.

Program TRIODE1 downloads in a few seconds. No unzipping inconvenience. Run immediately

The USPatent and Trademark Office has a great search engine -- www.uspto.gov
The best time to access it is on Sunday morning. I don't know if it's still
the case, but you did need to have "Quicktime" installed to view the
diagrams.

The USPTO also takes credit cards over the web to order complete patents and
they usually arrive in a couple days. I think that it's one of the best
things the governmetn does (but damn those pharma companies with their
hundreds of claims clogging up the works.)

That one dates from 1946 or 47. I have about four issues of QST
from that era, and there is an article about pulse-counting detectors
in one. I'm sure it references the patent, and is either written by
the inventor or mentions it. If I felt like digging, I could find it.
Someone with that era of QST on CDROM could dig it out, and make it
easier for you to dig out the patent.

In searching for the older ones, there is a certain art to using the
search engine. It helps to have alternate terminology in mind for
defining your search, names of inventors and companies, rough date
ranges, etc.

I had looked up some patents my father had worked on, and did not find
all of them in my initial search.

Happy trails,

In article <utb4imkhi8h9ae@corp.supernews.com>, Roy Lewallen <w7el@eznec.com>
writes:

>I've built DC receivers without an RF stage (using a diode ring mixer)
>and found the noise figure to be entirely adequate up to about 20
>meters. On 15 meters and above, an RF stage would be a good idea.

A diode mixer of any kind is passive. Its conversion gain is
therefore negative. There's a trade-off there insofar as sensitivity
is concerned: Eliminating gain ahead of a mixer requires more
gain behind the mixer...a very low-noise AF amplifier behind it...
which requires very considerable shielding and layout to keep
from picking up all kinds of EM garbage.

A ring or bridge diode mixer can be made to keep most of the LO
out of the input circuit (it is better than a regenerative detector and
far better than a superregen), but it isn't perfect, either. An RF
amplifier ahead of it brings such LO leakage down to levels only a
lab setup can measure.

>The
>MC1350 is a very noisy amplifier, so I wouldn't recommend using it as an
>RF stage. Or as an IF stage unless you have a fair amount of low noise
>gain ahead of it.

I beg to disagree. The MC1350 die is based on the MC1590 metal-
can-mounted original. For both the 1350 and 1590 the Noise Figure
is 6 db at 45 MHz, 7 db at 58 MHz in the factory test circuit which
has 50 Ohms in and out, bandwidth of 4.5 MHz...lower-frequency NF
is a bit better. Power gain with tuned circuits is easily 50 db at low
VHF and that translates to a voltage gain of about 316 times.

At a 6 db NF the noise power added by the amplifier is close to 3
times (in power) that of an ideal no-noise amplifier of the same power
gain. The input of a 1350 or 1590, each side of differential input, is
5 KOhms in parallel with about 2 pFd. The equivalent noise voltage
of just a 5 K resistance with a bandwidth of 3 KHz is close to 0.5 uV
at slightly-hotter than standard temperature of 290 Kelvin (allowing
for some IC heat build-up). Assuming a 6 db NF, the equivalent
input noise would then be about 0.87 uV (SQRT(3)*0.5uV) just from
the amplifier stage. Combined (since random noise power always
adds), that would be a total of about 1.0 uV equivalent across the
5 K input resistance of the 1350/1590.

Since the input resistance is moderately high, a 1:10 turns ratio
input transformer nicely fits a 50 Ohm to 5 KOhm impedance

match, coax to IC single-ended input. That would make the equivalent noise voltage at the 50 Ohm level about 0.1 uV for a source resistance plus that added by the IC. That should fit a normal sensitivity criterion established by existing receivers for a 3 KHz bandwidth. In actual practice on HF bands from 5 MHz and up, the equivalent input noise was found to be about 0.2 uV at a 3 KHz bandwidth...but that may be due to home workshop instrument calibration tolerances.

[I prefer calculations at voltage levels rather than write a bunch of minus exponents for powers...others will differ on method but all come out to be the same in the end]

The 1350/1590 isn't the "best" for extreme S/N but it is quite acceptible on HF where the atmospherics and ambient EMI is often above 0.2 uV at the antenna. That IC isn't the "best" for intermodulation but a tuned input and output circuit helps that. Input and output admittance is very forgiving of matching and tuned circuits handle the parallel capacitances at each end. The gain control range is claimed as 0 to 60 db attenuation but I would suggest that 0 to about 45 db is more practical and that is on par with existing RF gain controls on existing receivers. That IC is not all that swift on extremes of temperatures to military environments (Hughes Missle Div. needed more stability than the MC1590 provided), but less-stringent vehicle environments and room temperature locations should be just fine.

Motorola designed and produced a number of ICs that were intended for consumer electronics, particular TV receivers. The competition in consumer electronics is fierce and, eventually, Motorola stopped and sold die rights of some packages to other IC manufacturers. That isn't a black mark on the IC design, just a hard fact in mass marketing.

I personally prefer an active device that doesn't have curlicue-shaped admittance/impedance curves over a frequency range. Makes matching over wide frequency spans MUCH easier and the 1350/1590 behaves well in that regard...forward trans-admittance is nicely flat up to 60 MHz with little fall-off at the high end. Reverse is very low and the only possible feedback comes from inattention to reasonable physical layout.

The separate gain control pin works very well as an LO input for a mixer, either balanced or unbalanced. Motorola didn't publish much information on mixer circuit applications so that must be breadboarded and checked. Conversion gain is not a problem. 3rd Order IP is low; one can't always get everything for $1.19. :-)

3934. W7EL 40m optimized QRP VFO help please!

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-11-18 02:30:40 UTC
From: Mike Srock <msrock@chartermi.net>
Message-ID: <utgk6deq9v0jec@corp.supernews.com>
Source record: 39797

Hi Group.

I am building an optimized W7EL 40 meter QRP rig from the 1994 ARRL handbook.

I am not good with the dead bug construction so I designed five 2 inch square boards
using winboard by IVEX. This kept me below the 100 pin per board limit on the demo and
made it more modularized. (I can provide the board designs to anyone who would like to
try it.) It will all fit into a 2x3x5 project box when done with enough room for a keyer board too.
I actually finish construction of the boards a couple of years ago and I am just now getting back to it.

Anyway here is the problem. I can't seem to get the VFO to oscillate to save my life.
The vfo board has all the parts associated with the 2N4416 very close together to mock as much
as posible point to point construction.
I have tried the following things:.....

I have swapped out the 2N4416 with a MPF102. I also tried some others I had around .(just because I had some)

I have modified the board design to compact the parts for the oscillator even more and move the
coil closer to the FET.

I have rewound the coil and added one extra turn on each side of the tap. (just a guess)

I have tried adding a 4x6 pcb copper down under the board and connecting it to the VFO
ground for a ground plane.

I have rebuilt this thing several times trying different components.
I am ordering a handful of 2n4416 and 2n5486 FETs to play with.
The 5486 FET is supposed to be better gain than the 4416.

I believe I got better parts density with the pcb than I could have got with dead bug so I don't think that is the problem
I am lacking a ground plane and I don't know if that would stop it from working. Is there any modifications to the circuit
that need to be made to get it to oscillate without a huge ground plane? I can't believe that all hartley oscillators are built dead

bug. Maybe I have the wrong core for the coil. I am ordering a new one just in case.

When I use my signal generator to inject a signal before the buffers the radio receives signals and sounds pretty healthy so
I am really frustrated about not being able to figure it out.

I appreciate any comments that can help me get this thing going. I can email designs, drawings and pictures to anyone
interested in helping or using the board designs. If you would like me to email files to you please contact me directly.

Of course it is entirely possible I have made a mistake in the board design. An extra set of eyes or two might see something I
missed. (I hope)

And Roy if you are out here, I hope you don't mind me sharing my board designs. I am not taking credit for your work or asking
any money. Just sharing with fellow hams. If this is not ok let me know. I am hoping that more people will build the rig if we can
come up with a proven board design. It is much easier than dead bug for a lot of us!

I am looking forward to the responses!

Thanks!!

Mike

That oscillator, which comes from Hayward & DeMaw's _Solid State Design for the Radio Amateur_ is very forgiving, so something major is wrong. I've built many, many of them and haven't had one fail to start yet. Here are some things to check:

1. Are you using the right core material for your inductor?
2. Are you sure you have the pinout right for your FET?
3. Do you have the diode in backward?
4. Is the coil connected so the tap is about 1/4 of the way up from ground, not 1/4 of the way down from the top?
5. Are you sure your method of detecting oscillation is working? The oscillator does produce a healthy signal when it's running, though.

If you're sure you have these things right, then what I'd do next is to simplify the circuit to reduce the variables. Remove the 10k resistor going to Q2, and the 15 pF capacitor going to the RIT diode D1. If it doesn't start, then disconnect all the capacitors going to the top of the inductor L1, and temporarily tack in a capacitor of roughly 150 pF, connected from the top of L1 to ground. That's just about as simple as it gets, and I'd be very surprised if it still fails. If it does run with these simplifications, then replace one at a time until you find which one makes it quit, and figure out why.

I don't mind a bit your sharing your board. The rig was actually produced and sold as a kit by at least a couple of companies over the years, and many, many copies have been made of it.

Note there's an error on the schematic in the QST article (my fault) -- the phasing of T1 is incorrect. Also, D1 wasn't identified on the parts list. It's a 15V, 400mW zener. And on p. 18, Q7 - Q10 should read Q6 - Q9 respectively.

The only part in the probe that might be hard to get
is the P-channel FET. Any decent Schottky
quad can be used for the sampler and the rest
of the parts are ubiquitous.

Its the same problem in the 4815 vector
impedance meter (the newer 4193 uses N-channel
FETs).

You might try asking George Sandford (in NJ) about
your probes. He rebuilds 4815 probes, so he
should be able to work on 8505 probes as well.

[I don't have contact into for George Sandford]

Source record: 39801

This may be old news to some of you homebrewers/repair folks out there but I finally come up with a solution for probing PCB SMT components. The problem I experienced was in getting standard test probes into tightly component packed areas. The probes I have on hand are just too blunt.

At first I tried using alligator clips between the test probes and straight pins. The problem with this is that my alligator clips didn't make firm contact with the body of the pins. The other day I was in a 'goods' store and noticed sewing needles. These have a square head which my alligators can firmly grasp and very sharp thin points. Problem solved!

Hi.

I have a UTC power transformer marked R-5 that came in a home brew 6L6 P-P amp that I got on a estate sale. I wanted to use in a project I have in mind but do not have the exact specs. Any help would be greatly appreciated.

Thanks.

If you are looking for manufacturers and not retailers, here's probably the
top two companies. Maybe there's a couple more, but I forget right now who
they might be.

http://www.cree.com (HQ in Durham, NC)

Cree has a unique method of growing their own synthetic diamond substrate
(silicon carbide) to build their devices on. The thermal properties of
diamond are several times better than GAAS or Silicon, so they can make
smaller chips with the same thermal properties. They just can't make the
wafers as big.

http://www.nichia.com/ (HQ in Tokushima, Japan)

Nichia uses indium gallium nitride. If you are loking to order some, they
can take factory orders as small as $20. Don't know about Cree. Probably
have to go through a distributor.

In fact the two companies just settled a major law suit with a
cross-license agreement over LED manufacturing (including white).

That's probably more info than you were looking for, but what the heck!

Cheers,
Mike - KD6PKJ

If there is little clue what the connections are you can measure the winding resistances and you 'll quickly find the 117 V primary winding . If not 100 % sure connect the assumed primary winding to a variac and you find the other winding voltages and/or get confirmation of the primary winding.
To check the current rating of each secundary winding , by using light bulbs or resistors (car bulbs or resistors for filament windings) increase the load until the voltage has dropped by 5 % . That's a safe max load for that winding .
Be your own transformer 'detective'.

Frank gm0csz.kn6wh@ntlworld.com

Source record: 39807

I'm glad my posting brought forth such an informative and reasoned response. I'd like to add just a couple of other notes based on my limited experience.

The comment regarding LO radiation through the mixer is well taken. The only convenient data points I have are my little "Optimized" 40 meter transceiver (described in August 1980 QST), and a similar rig built for 30 meters. When receiving, they have nothing ahead of the mixer except the transmit LPF. The "Optimized" mixer is a homebuilt diode ring using 1N914 type diodes, and the LO level is high enough to switch the diodes quite well. The measured LO output at the antenna connector is -63 dBm, or 500 pW, or over 90 dB below the QRP transmitter output of 1.5 watts. Although this isn't necessarily representative of all diode ring mixers, no special care was made to balance it or reduce the radiation. Because of the rig's small size, internal wiring is short, but often routed in less than an optimum manner. This level of radiation shouldn't be hard for a casual builder to achieve. It's up to the builder to decide whether an RF amplifier is worthwhile solely for reduction of LO leakage, but I suspect that most people will be satisfied with this level. This isn't to say that there might not be other good reasons to include an RF stage.

In a rig similar to the "Optimized" transceiver, a considerably larger value of LO feedthrough (-44 dBm) was found. This was tracked down to the LO feeding through the transmitter stages, even though they were biased off. The path was effectively eliminated by shorting the driver stage collector to ground with an SD210 DMOS FET when receiving. After the modification, the LO leakage is about the same as the "Optimized" rig. This rig uses a Mini-Circuits TFM-2 mixer.

Regarding using the MC1350 as an RF stage, the user should be aware that the noise figure of 6 dB or so is valid only when it's running wide open. When the gain is reduced 20 dB, the noise figure rises to about 15 dB, and with 30 dB of gain reduction to 19 dB. This isn't as bad as reducing the gain with an attenuator right at the input, but if the rig is designed with excessive RF gain so that the MC1350 isn't running wide open, the noise figure could easily get bad enough to reduce performance even at HF. I've used it as an IF amplifier and find it to be a very handy device.

One final note on using the MC1350 as a mixer. Any device used as a mixer for a direct conversion receiver should be carefully evaluated for immunity to AM demodulation. This is one of the major potential problems with DC receivers. Tests should be done with various source impedances as well as differing signal levels, not just under 50 ohm laboratory

conditions. In the process of designing what became the "Optimized" rig, I found the diode ring mixer to be the best in this regard, and some time later Rick Campbell came to the same conclusion after his own evaluation of various candidates. Some high-level switching mixers available today might be as good or better, but they should be carefully evaluated before being pressed into service. AM demodulation generally isn't a problem in superhet rigs, so this property of a mixer is often ignored when evaluating mixers for uses other than DC receivers.

Date: 2002-11-19 00:01:56 UTC
From: Mike Srock <msrock@chartermi.net>
Message-ID: <utivrj7tp63k9a@corp.supernews.com>
Source record: 39808

Hi Roy.

Good suggestions. I will try them out.
I am ordering new FETs and a new core.

I have checked the pinouts on the FETs a bunch but I will check again.
The diode is connected the right way.
The coil is installed as described.
I am using a 100mhz scope to check for oscillation. I checked it against my sig gen before testing.

I will try your other suggestions too. I am hoping it is the core.
Should it be T-44-6?

I am using the schematic out of the ARRL handbook from 94
Is that one correct? The 15v zener is listed.

Thanks Roy!

I will post progress.

Do you snip the end (the thread end) off the end of the needle so as to grab the pin?

Hi Jack,
obviosly, they are the needles for sewing machines, not for hand sewing.

Hi Corny,
I remember an article about making triodes from car bulbs. The guy used a classic two-filament bulb - I don't know whether from headlights or from end lights. He covered a part of the glass jacket with metallic foil - this was the anode. Yes, hot glass leads electrons fairly well. One of the filaments was a directly heated cathode, the other filament was the grid. The guy remembers he could read newspapers in the glow of his radio...
It may be a problem to get a suitable bulb nowadays. It should be a vacuum type. Gas filled or even halogen ones seem to be no good. Both filaments have often a common lead, but you need to separate them. Nevertheless, this may give you an idea.

Actually, it'll oscillate fine without the diode, so you could disconnect it for a test. But the temperature stability will be rotten, so don't leave it off for real operation.

> The coil is installed as described.
> I am using a 100mhz scope to check for oscillation. I checked it against my
> sig gen before testing.

That sounds ok.

> I will try your other suggestions too. I am hoping it is the core.
> Should it be T-44-6?

Yes. The material (type 6 powdered iron) is the important thing; a different size will affect the frequency but it should still oscillate. A type 6 powdered iron core is yellow with a glossy finish. Type 2 (red) will also work, but with slightly fewer turns and with a poorer temperature coefficient.

> I am using the schematic out of the ARRL handbook from 94
> Is that one correct? The 15v zener is listed.

It took several attempts to get the buffer right, and I submitted an improved design along the way. (In the improved design, the feedback resistor is 27k and goes from Q3C to Q2B, the 10 pF capacitor is gone, and T1 phasing is unimportant.) I'm sure we'd gotten it right by '94 -- in fact, I didn't realize it was in that recent of a Handbook. It was in for a couple of years after the QST article, then was out. They must have run it again for a while.

> Thanks Roy!

They are more expensive, of course, but you can buy small needle-pointed spring-loaded probes specifically made for this type of measurement. The spring-loading helps prevent the tip slipping. Tiny clip-on probes are also available.

The RTMA published a standard color code for transformer leads in my 1953 ARRL Handbook. If the transformer is still in the circuit, this may be obvious, but here it is:

Black: Primary
If tapped: Common: Black
Tap: Black and Yellow Striped
Finish: Black and Red Striped
High Voltage: Red
Rectifier Filament: Yellow
Center Tap: Yellow and Blue Striped
Filament No. 1: Green
Center Tap: Red and Yellow Striped
Filament No. 2: Brown
Center Tap: Brown and Yelllow
Filament No. 3: Slate
Filament No. 3 Slate and Yellow

From: Tom Coates <tecoates@comcast.net>
Message-ID: <wJGcnbiLOM1y20egXTWcpw@comcast.com>
Source record: 39816

Ooops. Last line has a minor typo. This is the corrected version:

Black: Primary
If tapped: Common: Black
Tap: Black and Yellow Striped
Finish: Black and Red Striped
High Voltage: Red
Rectifier Filament: Yellow
Center Tap: Yellow and Blue Striped
Filament No. 1: Green
Center Tap: Red and Yellow Striped
Filament No. 2: Brown
Center Tap: Brown and Yelllow
Filament No. 3: Slate
Center Tap: Slate and Yellow

I wonder if it is possible to estimate power capacity by comparing the weight of the unknown transformer to the weight of a known item, perhaps from a catalog. This would provide a check on Frank's helpful suggestion.

Several months ago I read an (old) article about building an oscillator
using a 6H6 (IIRC; a dual diode) by using the metal shell as the plate,
so the basic idea sounds solid.

I'd give a cite for the article, but my house is still up on stilts
while the basement is being replaced, and all my ham stuff it up there
with it (I've lived in a detached garage for 9 weeks today!)

An LO leakage of -63 dbm should be in the "stealth" category!
:-)

A four-diode ring mixer will have the lowest LO leakage to the
input with a trifilar input transformer. LO injection at the
center of the secondary winding should be at least 40 db down.
A balanced input transformer (trifilar winding) is very easy to do
with a toroidal core and a hand drill (electric or manual). Cut
three lengths of coil wire to about a quarter wavelength of the
highest frequency expected, secure one end in a vise or similar,
chuck all three in the drill and wind it up to maybe three or four
full twists per inch. Cut off the chuck and vise ends, wind the
toroid, buzz out which wire was which with an ohmmeter. For
a further buzz check, make sure there aren't any shorts
between the lengths. Single-enameled coil wire is surprisingly
resistant to damage this way every place but at the ends.
Quadrifilar winding can be done this way for a 2:1:1 transformer
having the two primary windings in series.

>Regarding using the MC1350 as an RF stage, the user should be aware that

>open, the noise figure could easily get bad enough to reduce performance
>even at HF. I've used it as an IF amplifier and find it to be a very
>handy device.

Correct, but if the RF amplifier stage has deliberately-reduced gain
as for AGC or manual RF gain adjustment, the amplifier-added
noise-equivalent doesn't matter as much since the input signal
level will be higher. Looking at NF in db for various gains, using
the 1350/1590 as an example (it will apply to any other amplifier
but with different numbers):

Given a 300 K ambient, 3 KHz BW, and 5 KOhms input R, the
noise voltage is about 0.5 uV or 50 x 10^(-18) W. Noise Factor
(db) represents the additional noise added to thermal noise by
the entire amplifier and that adds in power terms, not voltage.
For 6 db NF, the equivalent total noise power at the input is
249.1*10^(-18) W [(50 + 199.1)*10^(-18)]. For 15 db NF that
would be a total of 1.63*10^(-15) W and for 19 db NF that
would be a total of 4.02*10^(-15) W [50 + 4022]. In converting
that to uV times gain for an output voltage, the example would be:

50 db gain, 6 db NF: Input equiv.noise = 1.12 uV, output = 354 uV
30 db gain, 15 db NF: Input equiv.noise = 2.86 uV, output = 90.4 uV
20 db gain, 19 db NF: Input equiv.noise = 4.48 uV, output = 44.8 uV

Note: The example uses a 5 K value for internal resistance in
the 1350/1590 device. If there is a 1:10 turns ratio coupler to the
input, the equivalent noise voltages referred to the antenna input
would be 10 times less.

The output can be related back to the input to compute a signal+
noise to noise ratio, generally accepted as 10:1. For a theoretical
0 db NF input, only thermal noise at input, that level would be
4.5 uV. At a 6 db NF plus thermal noise at input, the sensitivity
level would be 11.4 uV. The comparison category has to enter in
after that.

If the reduction in active device gain is to hold a certain output level,
then an increased NF (as above) only has effect on signal-to-noise
ratios at maximum gain...reducing the gain also reduces the total
equivalent noise at the input - more than the NF value indicates - to
hold output signal level (or even close to that). There are other
criteria, of course, but the general effect is that controlled gain
reduction just reduces the noise.

>One final note on using the MC1350 as a mixer. Any device used as a
>mixer for a direct conversion receiver should be carefully evaluated for
>immunity to AM demodulation. This is one of the major potential problems
>with DC receivers.

I will agree that input signal levels to any active mixer must be kept
below their IP but a differential input active mixer would concern

itself with common-mode input distortion. Other than that, I'm not quite understanding what was meant above. A direct-conversion receiver will handle both DSB and SSB AM. I can understand AM broadcast problems...a friend lives close to 50 KW KMPC station in the middle of San Fernando Valley (the only sizeable BC station in the midst of a packed urban area here)...that signal tends to creep into most any bit of electronics within several blocks. :-)

>evaluated before being pressed into service. AM demodulation generally
>isn't a problem in superhet rigs, so this property of a mixer is often
>ignored when evaluating mixers for uses other than DC receivers.

Few active devices are categorized at all for mixers yet nearly all differential input active devices with a separate common gain control will function nicely as a mixer. It's not a complex task to measure one separately to get performance values, even with just one test signal generator (LO input to common gain control pin part of the setup).

A suggestion on configuration of a direct-conversion CW receiver with very high-level IP: Have the LO run the same with both Rx and Tx, key-down turns on the Tx output stage which can be coupled directly out to the antenna through a toroid transformer arrangement. That transformer would be essentially a directional coupler connection and would eliminate any antenna switching or break-in circuits. The only warning would be the Tx output level and the maximum mixer input levels using a diode ring, that level determined by the directivity of the directional coupler arrangment. Probably been done before...:-)

Ok, It oscillates!!!

I removed the 10k and 15 pf and it was still dead.
So, I removed all the caps up to Q1... Success!!!
I started putting them back starting with the 12pf.... ok
then the 30 pf, still good!
When I put the 220 back it went dead again.
It is labeled 221k. I believe that this is a 220pf. I am not sure why the
VFO doesn't like it. I will try a different one.

The schematic in the 94 handbook appears to have the changes you described.

Back to the Variable cap, CQ a few years ago had a article on building
them from copper pipe. I don't have the issue right now, I'm in the
middle of a move.

>. . .

I believe your "common-mode input distortion" is what I'm calling (by its symptomatic name) "AM demodulation". Unless a mixer is perfectly balanced, there will be some second order distortion, and of course none are perfectly balanced. When presented with an A.M. signal, the result will be demodulated audio at the output of the mixer. In DC receivers, unlike superhets, this can't be separated from the desired signal, so is amplified along with it. AM signals can be huge -- I've measured KGEI in the San Francisco area (at 7335 kHz as I recall) at 0.25 volts RMS at my antenna terminals here near Portland under unusually good skip conditions. And with DC receiver audio gain typically exceeding 100 dB, even extremely inefficient demodulation is plenty to result in the demodulated audio overwhelming the signals you're trying to hear. In Europe, the situation is much worse, especially on 40 meters. So a DC receiver's mixer has to withstand these very strong AM signals (those that get through whatever front end filtering is present) without generating any detected audio. Anyone who has made a casual DC receiver has almost surely heard this background of broadcast audio unless he's fortunate enough to live in an isolated area. And even a fairly strong diode ring gets overloaded quite easily by AM stations in Europe unless relatively sharp filters precede it.

Of course, you can reduce the required audio gain if you add an RF amplifier. But then the signal is larger going into the mixer, which can aggravate overload. I feel the best approach for a DC receiver is to keep the signal at the mixer input as small as possible, even if it means you need more audio gain. Of course, the emphasis of my work on DC receivers has been for backpackable portable gear, where current drain has to be kept reasonable. If one has the option of dumping a watt or two into a mixer, the tradeoffs become weighted differently.

I can't recall the formula, but it is possible to calculate the power rating of a transformer from the size of the iron core. Maybe someone else here knows the equation. It is usually used for transformers in KW class amplifiers, so I do not know how accurate it would be for small ones.

Another good guess would be from the size of the wires. This would be the windings, not the leads to the outside world (sometimes the winding wires are brought directly out, however). Of course, I would not want to take one apart just to see what wire size was used.

Beware that those meters likely need a expensive calibrated shunt
resistor to display the correct current. By themselves they are just mV
meters.

I agree with Roy. The IP3 rating of a mixer describes how off frequency signals can mix together to create on frequency junk which will be heard in the rcvr audio. I have heard some describe the situation on 40m in Europe
as a constant "roar" in the 40m cw band as all the very high level short wave broadcast signals above 7.1 MHz mix together to create a wall of noise
in the cw band due to receiver IP3 short comings.

I am not sure what the IP3 rating of a typical diode mixer is, but suppose that
it is +25 dbm. A rule of thumb is that two signals about 23 db lower than that,
spaced apart appropriately will create a distortion product signal in the audio
passband of the receiver. In this case, the signal would have to be about +2 dbm,
which is extremely stout.

The way IP3 works is that for every 1 db of gain introduced in front of this mixer, the
IP3 capability will decrease by 3 db. So if you placed a MC1350 with 60 db of gain
in front of this mixer to use as an RF amplifier, the IP3 rating of the mixer would
decrease by 180 db. You now have a mixer with an effective IP rating of -155 dbm, with
RF distortion products being produced by signals as small as -178 dbm. That is quite a
change!

Since best case receiver sensitivity of a cw receiver with a 500 Hz audio filter is
-148 dbm, and since 40m back ground noise doesn't really get any better

than -115 dbm,
such a configuration would create IM images from every signal and all the noise in
the passband of the receiver front end mixer for perhaps a MHz or two on either side
of what the receiver is tuned to. This is really, really, really, not good.

Because of this problem, good receivers (DC as well as superhet) try to minimize the
receiver gain in front of the main receiver filter.

In a superhet, this is the crystal filter. The MC1350 IF amp is usually placed
after the crystal filter, which is why it is referred to as an IF amp. Its large gain
has been protected from off frequency signals by the selectivity of the crystal
filter.

In a DC receiver, this is the audio filter, either a passive L/C filter such as used in the R2
or an R/C active filter, or simple audio gain shaping. This filtering limits the large signals
that will be seen to only the receiver passband, removing the large off frequency components,
and thus these off frequency signals cannot mix together to create distortion products
in those later, high gain, overload prone receiver stages.

The main message here is to introduce tight filtering as soon as possible in the receiver gain
structure, and minimize the gain in front of that filtering.

In receiver design there is a classic trade off between best receiver sensitivity (usually
involving the use of RF preamps in front of the first receive mixer) and best high level
signal performance (usually no RF preamp and/or the use of an attenuator in the RF front end).
Receiver pre-amps produce gain ahead of the first mixer, hurting IP3, but improving sensitivity.
Hence the tradeoff. The Adventure Radio Society (ARS) web site has a measurement of this trade
called the receiver factor. It takes into account the IP3 (high level signal capability) and the
noise figure (weak signal reception capability) of the receiver. Ideally, we want both. We want
to be able to work an extremely weak signal in the presence of huge signals all around.

On 40m, even in the quietest of times, band noise is high enough that a RF preamp will not
improve sensitivity, as the noise is way above receiver sensitivity.

DC receivers are quite capable of beating the best commercial rigs in the above sensitivity/high
level signal tradeoff while at the same time consuming only a tiny fraction of their receiver power.

Source record: 39836

I have an old 49 MHz cordless phone.

I have figured out what the basic stages are in the circuit, and there is a round flat package in the input stage of the receiver. It is maybe a little smaller than a dime and perhaps 3 to 4 times as thick, and is 'silver' color.

My guess is that it is a SAW filter. From what I know about the things, they are not tuneable, so it would have to cover the entire 'Cordless Phone Band', or at least the channels used by this receiver.

Do you think my guess is right? What sort of things could this be used for? Has anyone on this group played with SAW filters?

Jim
N8EE

PS. I should have saved the second cordless phone. Then I would have two filters!

Close Frank,
It uses nylon screws as sliders with air dielectric(sp), there was a
table of working volts & pf for each combination of tubes. I was looking
at building a tube rcvr, a 360 pf at 250 volts took a total of 12" of
tube. If I used 2 sections (in a U) it took 6" etc. It was suggested to
use a chunk of "all thread" for the tuning motion.
Every thing was from the local hardware store (or super store)

I have received a couple of emails asking how to get started.

I have three basic recommendations:

1: Learn the RF/IF circuittry of the phone, what the RX LO should be, what the IFs are (they usually have a two or 3 stage IF).

2: Get datasheets, they can be an invaluable resource to figuring out what the frequencies are, how to program the PLLs for the frequencies desired, and even sometimes have sample circuits.

3: Read up on cellular phreaking philes, there is a lot of good info there on how cell-phones work.

A simple capacitor to build would be a neutralizing type condenser.
Build a u shaped platform, hang one large square or circle of metal in
a stationary position on one "leg" of the U and then attach another
piece of metal to a section of allthread that screws thru a bolt
mounted on the other "leg" of the U, I have not tried this yet but
have seen a few neutralizing capacitors and they look fairly easy to
homebrew. You could probably rig up a nice looking slide type dial
using this method too, well nice, probably not nice looking, lol.

I built a vernier drive a couple of years back using a very large
plastic wheel mounted on my capacitor shaft and then used a u shaped
metal holder to mount a knob and a shaft. I used a large rubber band
between the shaft and the wheel, I forget the ratio but it was very
high. nasty looking and probably not the quality you guys who are
really into radio require but for I was quite proud of it.

Take the back off the microphone and look.......

Also, the audio out will usually be the wire that is wrapped in the braided shield, so try stripping a little off the end of the cable and see which wire that is (possibly either yellow or white...)

As far as I can tell, Gary, it is in the input stage before the mixer.
There are some numbers on it, one of which is forty-something (at
work now, so I can't run and look at it). This leads me to beleive
that it is wide enough to cover all the channels---the receive
channels anyway---so it would be a few hundred kHz wide.

One possibility is as a first IF filter for an HF receiver, maybe with
a tuneable second IF. Or possibly put it after a cable TV tuner and
have a mulitband VHF receiver, with appropriate detector stages of
course.

=====
To add to the above : If a variable capacitor is involving a screw type
mechanism ,a suitable 'dial' can be made of a 10 or 14 turns potmeter knob
(for example those made by Beckman)
Depending on the number of turns the screw has to make to cause the required
change of capacitance (which largely depends on the screw's thread pitch) a
'reversed' co-axial reducer can be applied in series with the 10 or 14 turn
dial knob.
These rotary reducers normally have a 3:1 or 6:1 ratio. Using for example
the latter in reversed mode e.g. 1: 6 , a ten-turn knob would be able to
rotate the screw type mechanism 10 * 6 = 60 times,providing a resolution of
1 in 10*100= 1000 since the dial knob can be set to any of 100 positions for
any rotation. In this way
the variable capacitor (for example used for tuning) can be set accurately
with a high resolution.

There's plenty of circuits around but it is indeed a bit difficult to find a CW/75 watt/multiband/vfo rig project. I just went through the search and the best I could find were in the mid-60s ARRL handbooks. In the '65 Edition for example, there is a 12BY7/1625 project and a 6AG7/6146 project plus a VFO.
I wound up buying an old Harvey-Wells boatanchor xmtr to restore and will modify a nice/junk 5MHz VFO that I have sitting idle.

Gang,
Who makes frequency counter kits these days? I'm looking for one
that does, say up to 500MHz, and has a 7 seg LED or LCD type display.

Thanks

Bob WB0POQ

Both good suggestions. Also if you have a Voltmeter (Ohmeter actually) put
it in the lowest range. Put one lead on common (shield) and tap the other
lead to the unknown audio line. You will hear a sharp click when you find
it.

This does not work on all mics however.

is quite
>a change!

...except that IP3 applies to ANY amplifier device added in front of the
mixer so
the intermodulation condition goes to the front-end instead of the mixer.

[a
practical wide-open gain of the 1350/1590 is about 50 db in voltage, not 60
db]

One cure for out-of-band signals is a passive band-pass filter. For a 500
Ohm
impedance, 20% BW, 3-section, "top-coupled resonator" BPF with
capacitive Q of 1000, inductive Q of 100, these values would be:
L1 = 1.153 uHy, C1 = 400 pFd (both in shunt)
C2 = 30 pFd (series)
L3 = 1.102 uHy, C3 = 390 pFd (both in shunt)
C4 = 30 pFd (series)
L5 = 1.153 uHy, C5 = 400 pFd (both in shunt)
With the given unloaded Qs, insertion loss at 7.148 MHz (geometric band
center)
is 1.9 db. Higher Qs result in less insertion loss. Insertion loss
variation within
the 40m bandpass is less than 0.5 db with the given unloaded Qs. The most
dramatic effect is the attenuation at AM BC, a theoretical 144db at 1.0 MHz
with about 98 db at 2.67 MHz. In practicality such attenuation won't be
attained
without something heavy (such as a double nested cast aluminum box) in the
way of shielding.

Tuning of this type of filter is absurdly easy: Short the inductors not
being tuned,
adjust the unshorted inductors for a resonance at band center (7.148 MHz).
A
dipper of some sort will work or use 10 Ohm or so resistors in place of
shorting
jumpers and brute-force feed the filter with a high level signal to peak the
coils.
The "brute-force" method is preferred due to de-tuning of dippers from over-
coupling.

For a 50 Ohm input-output BPF, multiply the Ls by 10, divide Cs by 10. For
the
500 Ohm filter values with a 50 Ohm input, replace C1 with a shunt-series of
C1A (shunt) of 1200 pFd, C1B (series) of 600 pFd. That yields an
approximate
input Z of 60 Ohms (actual Z of most BPFs varies considerably over
passband).
>
>Since best case receiver sensitivity of a cw receiver with a 500 Hz audio
filter is
>-148 dbm, and since 40m back ground noise doesn't really get any better than
>-115 dbm, such a configuration would create IM images from every signal and
all
>the noise in the passband of the receiver front end mixer for perhaps a MHz or

>two on either side of what the receiver is tuned to. This is really, really, really, not
>good.

Agreed, but that raises a point on just exactly what is wanted in the way of performance: High sensitivity or high IP3? Trying to do both at the same time
requires considerably more work in the design-breadboard stage. Ulrich Rhode's
book on that covers it well, paying a lot of attention to all kinds of IM nasties.

If input sensitivity is on the order of -115 dbm, then a practical diode mixer of
8 db conversion loss would put the mixer output level at -123 dbm. The "base-
band" output of a direct-conversion mixer would be at about 0.16 uV maximum.

That low a level, even at audio ranges, is not trivial. Shot noise, 1/f noise, etc.
at audio frequencies start manifesting themselves and that is an added problem having nothing to do with RF stages.

>Because of this problem, good receivers (DC as well as superhet) try to
>minimize the receiver gain in front of the main receiver filter.

:-) That gets into a (sometimes) subjective definition of "good."

Any receiver with high IP3 -and- high sensitivity criteria has to pay attention to both high-level input linearity (for minimum IM) and thermal noise at the front end. For portable "QRP" applications needing low primary power drain there has to be some compromise. In general, a high-IP3 diode mixer has a high LO injection level which requires higher power drain for the LO; for +20 dbm LO input (100 mW), the LO circuit might consume 200 mW of primary power (total including VFO), more for higher LO level. An RF amplifier ahead of the mixer might have a 12 mA at 12 VDC power demand or about 144 mW from the supply. It's a compromise depending on the type of transceiver, where it is used, kind of primary power.

>DC receivers are quite capable of beating the best commercial rigs in
>the above sensitivity/high level signal tradeoff while at the same time
>consuming only a tiny fraction of their receiver power.

I'll agree in general terms, but consider an application such as a portable QRP transceiver. If power demand is an important criterion, then many of contemporary line-powered transceiver features cannot be used unless such features are available in newer 5 V and 3 V SOC devices (DDS chips, etc.). Digital frequency display takes some power, even with CMOS drivers and LCD panels...and such features often involve more complexity than the RF and AF circuits.

Can direct-conversion rigs "beat" conventional receiver designs?
At the risk of controversy, I'd say no...they can MEET them with
a lot of care and attention. Their simplicity is certainly a factor,
another thing to consider in homebrew projects.

NOW AVAILABLE ** New Program STUMATCH.exe"

This program assists with the design of stub-line transformers used for such purposes as matching the feedpoint impedance of radio antennas to the Zo impedance of the transmission line from the transmitter. The program is applicable to both balanced-pair and coaxial lines. These and similar types of transmission line transformers have traditionally been designed with the aid of Smith Charts. The superiority of this program in respect of time, operating simplicity, accuracy and user appreciation is clearly seen.

Download STUMATCH from website below.

Looking at your email address, are you affiliated with NEI (the tech school) in Minneapolis? I graduated there in 1983 and took more courses in 1988.

Anyhow, Digikey has an Intersil chip that was a freq. counter, totalizer, ratio counter, etc for $30 something, some years back. Might check their website, I believe www.digikey.com.

You might be able to find some 74S series chips to make a divide by 100 counter since the Intersil chip only goes up to 10 MHz.....

Actually, here is what I found at DigiKey....

ICM7216DIPI
IC COUNTER/TIMER
FREQ 8DIG 28DIP
Intersil

Contact our Technical

Support Dept at

1-800-344-4539

Sorry for the formatting (cut & paste). It is an obsolete part, but maybe they have or can still get. About $29. They also used to have a data book for these chips...might still be able to get it also.

You might take a look at the following link:

http://redhotradio.com/

and follow the link to the NorCal 30. It uses phasing to get single sided
reception from quadrature detected DC audio. This DC transceiver design draws
only 13 ma but in most respects has a tougher receiver than anything currently
on the market.

Since this design emphasizes both low cost and low current drain, it is certainly
possible to do even better.

I have an old low voltage power supply which uses a uA78GKC (TO-3 case 4-pins) voltage regulator that I need to replace.

I haven't been able to locate a new one or find a crossover.

I'm hoping that I can find either that piece or a direct replacement so I don't have to rebuild the whole board.

Would anyone know where I can find a uA78GKC or a replacement with specs and circuit
information?

Bob,
Try here http://www.aade.com/index.html. This is the site for Almost
All Digital
Electronics in Washington State. He has some very compact and nice
frequency
counter kit. I bought the DFD4. This can be used as the frequency
display for a
homebrew receiver or transmiter. Or as a stand along frequency counter.
The
DFD4 goes from 0 to 2.0 GHz.

N5GPI,

You probably WONT find it in any cross reference book either. That's an old CTC part from probably the 70's. Let's see, Acrian bought CTC back in the early 80's, then Acrian went out of business sometime later. GHz Technology picked up some of the product line and continued to manufacture it for customers left hanging by the Acrian crash. You might check with GHz. Here's a good page you can visit and maybe match up the case drawings with what you have and go from there...

http://www.ghz.com/products/vhf.aspx

Oh yeah, earlier this year GHz was bought by Advanced Power Technology, but they still maintain their old web site. If you see something close, drop them an email and ask about your part. Maybe they may still have an old CTC catalog laying around and could give you some info from it.

The last hope to find out anything would be Richardson Electronics. They have been distributing RF power transistors for longer than I've been around. I think they used to carry Acrian and CTC parts way back when. You can find them at http://rfwireless.rell.com/.

73's and good luck! (You'll probably need some!)
Mike - KD6PKJ

UA78HCSC and UA78HG

Both of these numbers were found on 2 separate yet supposedly identical parts/units. They were 4 pin regulators used in a 5-15VDC 7 AMP Power Supply. Now, the HG number came from the manual itself for the power supply I purchased originally. The HCSC was on a spare unit I bought - found on E-Bay about a year ago. It may have been replaced and for all I know not quite up to par with the HG. I've never run the spare unit through it's paces yet. I don't have any listings to confirm or deny this. BUT if someone has these parts and willing to sell them, or know of a source thereof, I'd be happy to hear from them. OR something equivalent. As the other gentleman alluded to, I don't want to have to "redesign" these power supplies.

I saw the ads, too, Roger, and never paid them any attention

My reaction was, "Ho, hum... someone is trying to get back in the Heathkit business" and I assumed it would be a typical kit... buildable but with the usual compromises in performance, stability, calibration, reliability and such. With the quality of today's radios, who needs it? (Boy, was I wrong!!)

At the time, I was interested in the Yaesu FT-817 portable so began reading some QRP newsgroups. Bought an 817, in fact, and really loved it. But what I was reading caused me to look further at the Elecraft K2. QST's lab, for instance, said it had THE BEST performance, in the presence of close-in interference, EVER tested in their lab. In fact, as a result of the K2, they have since begun testing strong signal handling at 2KHz in addition to the old test of 10KHz .(I think that's right.)

Anyway, I bought and built mine nearly 2 years ago. Performance is superb. I have done A/B tests between it and my Icom 756PRO for a number of visitors to my shack. In dozen of cases we could (sometimes easily) copy a signal on the K2 that was not copyable on the PRO. Not once has the reverse been true. I never turned the 817 on again and finally sold it. And BTW, my PRO had the edge over the FT-1000D it replaced.

The K2 is a very small radio so many lesser-used functions are accessible via menus... not as convenient as having everything on a front-panel knob or switch but perfectly okay. The basic kit, before some of the later options, had no cuts or jumpers on any board. Exquisitely done design... several boards that all plug easily into each other. Building the kit was great fun and took about 45-50 hours for the radio, SSB, noise blanker, auto-tuner, and 160 meter kit. (my first kits in 30 years and with much worse eyesight now than then.) Some cuts & jumpers were involved with the later options like the RS-232 (computer control of the K2 and K2 output to your logging program among other things) and audio filter, though not objectionable. My 100-watt amp option will be installed next week giving me continuously-variable power from about 1 watt to 100. The overall size of the unit doesn't change with this option.

Everything you will need to tune it up, except a VOM, is included in the kit.

It is well worth a serious look!

The envelope continues to get pushed. Did you see Dan Tayloe's test results of the prototype NC-30? Seems like Fifield can't let Burdick out-do him! The receiver on the NC-30 just blows away the K2 (and everything else). Norcal expects to be kitting the NC-30 in January, and sometime later Red Hot will take it up.

So, maybe this time next year Wayne will be tired of hearing all the oohs and ahs about the NC-30 and come up with a K-somethingoranother to blow it away!

I think your best bet would be to build one of the typical MOPA
(oscillator-amplifier) crystal-controlled rigs from the '50s/'60s, and
then find a VFO at a hamfest or on ebay to add on. Do you have any
tubes that you want to use, or are you starting from zero?

BTW, most such rigs are going to use an 807, 1625, 6146 or sweep tube
final. Typically you'll be looking at 40-60W output. Just raise your
antenna another 5 feet and it will sound like 75W ;+) You can also run
two PA tubes in parallel to get your 100W out.

Let me strongly recommend that you join the glowbugs email list, where
the focus is on homebrewing and operating tube ham gear. The group is
quite friendly and will definitely help you with your project. Here's
the list info from the radio groups FAQ:

For homebuilding transmitters and receivers using tube technology,
there is the Glowbugs e-list; send an email to:
majordomo@piobaire.mines.uidaho.edu and only write:
subscribe glowbugs <your@address.here>

Come on by and we'll try and get you set up! I'll even pitch in a
5763 oscillator tube and a sweep tube PA to get you started if you
need 'em.

>counter since the Intersil chip only goes up to 10 MHz.....

From www.intersil.com, their ICM7216B universal counter IC is
still around (datasheet date is Feb 02). Intersil yields only four
distributors: Arrow, Avnet, Newark, and Nu Horizons. Only
Newark had any in stock (178 qty) as of late Thursday afternoon
and singles price was $34.72. The Intersil datasheet displays
several schematics. The B suffix is the all-purpose IC while the
D suffix indicates only frequency counting. Judging from longevity
in prior distributor catalogs and low quantities now, it might not
last too many more years in inventory. :-(

There are several divide by 10 digital ICs available as prescalers,
FAST, ACT, and HCT suitable. Any wideband differential output
amplifer handling relatively low resistance loads can work into an
R-S flip-flop for squaring-up the input (amplifier supply rails not
more than NAND gates used for the R-S flip-flops)...use Schnitt
trigger NANDs if desired, but not absolutely necessary.

A friend built one about a decade ago, still working well. For
really nit-picky accuracy in the time base (better than 5 PPM)
an external crystal reference oscillator can be used.

Hi there,

Save yourself some work and just clone the circuit of the Heathkit SB-1000
or the Ameritron Equivalent.

From memory, the imput impedance is about 130 ohms for a single tube.

cheers

Bob, just to confuse things further, My 1990 copy of International
Semiconductor Directory shows that Marconi Electronic Devices
producted a line of UHF Mixer and UHF Detector diodes with numbers
like CV7109 and CV 7180 up through numbers like CV8100's. I didn't
find your particular numbers though.

There are lots of good designs out there - main problem is what parts you have and what bands you want to use. I strongly suggest starting out on 80 and 40 meters, and also going for General as soon as practical.

Here are some classic designs, if you have access to old QSTs:

"All Band CW Transmitter For The Novice", QST, August, 1960. 6AG7 feeding 807 or 1625, 40-50 watts input. Rather compact - I'd use a bigger chassis. Plug in coils. Power supply requires a fairly high-voltage transformer if you want full power.

"65 Watts At Low Cost", QST, March 1961 and first edition of "Understanding Amateur Radio". 6K6GT feeding parallel 6BG6Gs, 65-75 watts input. Many other tube types can be used. Uses relatively low B+ and relatively common parts on a big chassis - lots of room for substitution, changes and experiments. Good for up to about 100 watts with an adequate power supply.

"An Easy To Build VFO" , QST, February, 1962. 12AU7A driving a 6AU6, output on 80 and 40 meters. Based on a design by W2YM design, but is more complete and easily used with most Novice-type transmitters of the era.

Please take KK6GM's advice about the glowbug reflector. Lots of good info and knowledgeable folks, plus sources of parts.

Better numbers, yes, but not a lot better. Still amazing, particularly
considering the simplicity and very low current drain.

The compromise in the NC-30 design is the relative lack of unwanted-sideband
suppression. And so far it's only a monoband design.

But just wait.......;-)

>on the market.

Thank you for the link. Interesting information even though no
NorCal kit was available. The schematic diagrams were fuzzy
in small details, not discernable enough when using Acrobat
5.0 for viewing.

As to being a "tougher receiver than anything currently on the
market," I will dispute that several ways. Let me begin by
saying I do not deal in radios nor am I promoting any radio kit
sales. This thread title reads "brainstorming designs for new
40 meter transceiver." I'll put on my "design review meeting"
hat, a familiar article on both sides of the meeting table.

The basic architecture of the NorCal30 could be adapted to 40m
monoband. There should be no problem dropping frequency.

The switched-multiplexer mixer concept is interesting (and
patented) but there seems to be more complexity there (VFO
tripling to get injection at 4X frequency of a direct diode ring
mixer circuit). This is an advantage for SSB but no discernable
advantage for CW. A superhet receiver with sharp crystal filter
of 300 to 500 Hz BW would have better skirt selectivity at the
so-called "image" on CW.

The claimed sensitivity figure uses a 3 db signal-plus-noise to
noise ratio, which is not the standard EIA test value of 10 db.
There is no guarantee that the "minimum discernable signal"
test level is accurately calibrated...is there a list of test
equipment in deriving this?

The claimed minimum discernable signal level of -136 dbm is equal to 35.4 nanoVolts in a 50 Ohm system. If the mixer conversion gain is 0 db (no loss at all) then that is equivalent audio of 35.4 nV peak on a random noise floor of 26.2 nV. That is hardly trivial for a new design even though it is bandpass filtered by later low-pass and high-pass active filters. If that coexists in the same box as a switching regulator, there must be adequate layout and shielding from switcher noise. Those are added problems for a new design.

I will remain skeptical on the IP3 values claimed for this mixer until proven independently. Higher RF input levels would manifest themselves as higher AF levels along the chain of four audio amplification blocks. With no gain budget tabulation versus RF input level, there is no quick verification that some audio stage might go into limiting or saturation from high RF input levels. I'm sure it is a good chain, but the fuzzy image of the schematic doesn't allow a good viewing of parts values to complete the evaluation.

>Since this design emphasizes both low cost and low current drain, it is
>certainly possible to do even better.

The specification for transmit power supply demand is 9.36 W (12 VDC at 0.78 mA) for a 5.0 W RF output. That is an efficiency of 53.4% for a Class C stage. Not close to optimum possible.

Use of a switching regulator to get more than one supply voltage is fine but the distinction on using only two large cells as a basic battery is not spelled out. Since the 3 V rail has much less current demand, a buck regulator to supply that from a 12 V battery source seems more efficient for portable use and make it compatible with 12 VDC vehicle electrical systems as an alternate power source.

"Whisper" low current demand circuitry can be applied to RF stages as well. My little Oregon Scientific clock radio tuning to WWVB has no power switch and its main current drain is the LCD panel. There are many similar applications found in today's consumer electronics market radios...such as the nice PR giveaway auto-tuning FM radio with clock from Analog Devices that I sometimes use (one battery cell).

<"design review hat" off>

Normally, "brainstorming" a new design should take into account as many possible ways to accomplish something with an addition of practicality necessary for homebrewing. All I've offered is some suggestions, some possibilities.

I don't sell radios or components in any form.

"Good" design of a system and all its circuits has to be
judged by the designer and his/her capabilities...each one
is unique and the criteria for each one is variable. If the
experimentation leads to something new and better in
some way, then that should be an excellent outcome.
If not, but the project works, then that is its own reward.

Just a brief comment. While IP3 is as important for DC receivers as for superhets, second order distortion (or imbalance, or common mode susceptibility or conversion) can easily be the limiting factor in DC receiver performance and usefulness. But because of the preponderance of superhets, this characteristic is seldom even mentioned, let alone evaluated. The result can easily be a DC receiver that looks fantastic on laboratory IP3 tests but that's unusable because of a constant jumbled background (or foreground) din of demodulated AM. It's not a little, minor effect. It's something that requires at least as much attention as, and probably more attention than, IP3 in considering mixer choices. And it can present at least as great a challenge to overcome.

Message-ID: <3DDF8655.7C802D86@cox.net>
Source record: 39730

The IP2 dynamic range for the Norcal 30 prototype has been measured at 104 db, which compares favorably with the top two current best receviers, the K2 at 101 db, or the FT-1000MP at 94 db (data taken from the ARS review of the K2).

Unlike many other DC rigs that I have built before, I have never heard demodulated SWBC due to front end overload when using this arrangement, which was indeed a pleasant surprise.

4018. ADDING TONES TO A YAESU FT-225RD

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-11-23 15:47:18 UTC
From: dss117@aol.com

Source record: 39731

I have a 2-m Yaesu FT-225RD and need to add a tone board for repeater use. I can get a nice tone unit from Com-Spec, but can't figure out where to conect it to the radio.
Anyone try this with this rig?

4019. Re: Looking to build a novice transmitter

You didn't mention your level of electronics knowledge or your experience in electronic construction, so I'm assumming you're basically competent at both and equipped with the basic tools, etc. That being the case, any of the projects recommended by the other respondents will work fine.

But don't think you have to look for "that perfect project" that has just what you're looking for -- many of the 50's -- 60's ARRL Handbooks had great sections that talked about transmitter circuits individually. After perusing one or more of these gems, you may want to use a Vackar oscillator (or a Colpitts, or a Pierce, etc.), followed by a buffer stage, followed by any of the popular low power PA stages of the time (807, 1625, 6146, 6DQ6, etc.). You may want to use a pi-net output coupling circuit, or link coupling. You may want to take into consideration what type antenna sytem you'll be feeding.

The point is, you'll have more options than trying to duplicate a project from an article or a handbook. And that leads to one of the many joys of homebrewing, trying out different stuff! And that leads to one of the greatest joys of homebrewing, learning new stuff!

Either way, You'll have a great time!

Good Luck & 73.....John, K9OF

4020. Using fundamental xtals for overtones

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-11-23 18:02:14 UTC
From: ae517@FreeNet.Carleton.CA
Message-ID: <arofr6$462$1@freenet9.carleton.ca>
Source record: 39734

If one were to use a fundamental xtal in an overtone
oscillator circuit, other than the frequency being offset
somewhat, would there be any difference in it's operation
w.r.t. a true overtone xtal?

I looking to build a reference oscillator, but it need
only be within a Mhz or two of 135 MHz, so I'm wondering
if I can use a cheap microprocessor xtal.

Well I'd like to thank everyone for their Help.. I've learned quite a bit from every one over the past couple of days..(making sure to save all the posts just incase i forget a tidbit of info).. All the links and Data have been really helpful... So now I'm stuck with the problem... In wading through all the info I've come across the 2n2/40..Nice looking setup and easy enough for me to reproduce (hopefully) so i may be building that as my Christmas present for myself I got side tracked from my initial task of designing my own txcvr.. :)... but now that i am back on track for now here is what I have concluded so far..

1.) Going from a 10k 10 turn pot to a Microcontroler adjusted voltage is not as easy or as cheap as i thought it would be.
2.) Tuning resolution is sacrificed for price reduction.
3.) There are 800 ways to skin a cat :)
4.) It's cheaper to use a reversevoltage diode then to buy all new parts when you hookup power backwards. well mostly new parts any way.. from XYL " Hey honey what's that smell??"
5.) I love this hobby.

I don't think that this unit has a backup battery. If it is anything like the IC-25, you need to have it hooked up to 12V all the time in order to keep the memories.

hello all,

have a question. i am putting together a novice AM/CW station here (knightkit t-60/r-55a) just for straight key nights and wanting to play am radio (plus, i have not even begun to gather parts for my 813's driving 813's tx, but that is another story.). anyway, question is, i have a siltronix model 90 vfo that i have had for some time and do not use. i was looking for a vfo for the t-60 and thought, why can't i mod the siltronix vfo for the ham bands. i have a few 243 crystals around, but would like vfo coverage. wanted 5 band coverage 80-10, no warc.

has anyone ever done this? or am i venturing into stupid here?

thanks in advance.

I'm not exactly sure but I think the Siltronix VFO would have a 5 or 6
Mhz output. You could probably push it up to 7 without much ado but to
get it down to 3.5 might take some more serious piddling.
I'm getting ready to perform the same surgery on an old Galaxy VFO.

I would be very interested in some stage-by-stage analysis
and spectral content in the NorCal 30 with high-level RF
input. The switched-multiplex mixer is certainly unique
enough...but it would appear (at first glance at a fuzzy
schematic) that successive audio stages would go into
limiting/saturation with high-level RF input. How would
that affect the preamp or phasing blocks insofar as
close, but not on-frequency RF input?

Generally speaking, you should expect reasonable frequency stability with the siltronix VFO which makes it tempting.

Personally, I'd suggest leaving it alone and mixing it with crystal oscillators to obtain the frequency ranges you need. Fooling with changing it's tuning range can work, but it can also be difficult to do on a commercial product. It would depend on the precise electrical and mechanical construction used by Siltronix.

True, there are a LOT of other approaches, some with very nice and clean outputs, but they usually involve a great deal more complex circuitry. Phase lock loops, Etc.

A simple mixer, using a double balanced diode mixer to reduce spurs, and some filtering after the mixer is pretty straightforward and would allow you to make 5 band coverage and so on with identical tuning stability and so on for each band.

Not only that, but adding a few other crystals to generate the proper frequencies would allow you to feed the Tx too eventually, and so you would have a transciever, of sorts.

4030. Re: Brainstorming Designs for new 40 meter txcvr..

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-11-24 00:00:41 UTC
From: Dan Tayloe <dtayloe@cox.net>
Message-ID: <3DE016DE.7C283ABB@cox.net>
Source record: 39743

The saving grace for this design is that the detector, besides having
only 1 db of loss, (which gives a 5 db sensitivity advantage over a
normal diode mixer), also has the advantage of performing its own
detection filtering. I.e., it has a settable bandpass detection
characteristic. In addition, the audio preamps have simple R/C
rolloff. The preamp rolloff and detection bandwidth has been optimized
for cw. That is it for filtering and gain until the R/C active filter.
The phasing stuff is unity gain.

Overall, it works well, even close in.

The differential properties of the post detector audio preamplifiers
also helps keeps out a lot of common mode crud. No special filtering is
required beyond what is normally done for power supply decoupling.

Low noise audio op-amps are very plentiful.

The design runs off 12v, which is converted to 5v and 3v by a switcher
chip for internal use.

That depends on the quartz crystal cut. "Overtone" crystals have a more pronounced harmonic vibration characteristic than more conventional cuts. There's a bit more on this at the crystal producers' websites but they don't appear to characterize the "cheap microprocessor crystals" for overtone operation.

>I looking to build a reference oscillator, but it need
>only be within a Mhz or two of 135 MHz, so I'm wondering
>if I can use a cheap microprocessor xtal.

I would suggest two possibilities: A Colpitts type with collector tuned to second or third harmonic of crystal fundamental, probably with a tuned buffer following it to boost harmonic level...or any fundamental oscillator with a multiplier stage following.

Since Jameco still sells the Motorola MC145151 PLL chip, that and a prescaler chip at the input would allow you to set the exact frequency of a VCO driven by the loop filter. More complicated that way, but frequency will be held very well to what you might want.

+40 dbm does not mean what you think it does. Measure the 3 db S+N/N MDS sensitivity of the receiver. Take two rf signal generators (nominally 20 and 40 KHz away from the receiver frequency) and increase both of their power to the point that a 3 db MDS IP3 spur signal is produced. To calculate IP3:

IP3 = 1.5*(Gen power - MDS) + MDS

If the MDS were -135 dbm and IP3 was +40 dbm, the two generators would produce a 3 db MDS spur at a signal level of only -18.3 dbm. This is of course no where near +40 dbm. I doubt the receiver front end could really survive 10 watts into the front end.

This is not to minimize the fact that an IP3 of +40 dbm is pretty good, it is just that it not obvious what that really means. It is certainly not obvious that two signals at -18.3 dbm could create a receiver spur in a radio with an IP3 of +40 dbm.

It is really, really hard to measure +40 IP3! I use a pair of HP8640b signal generators to make my measurements, and on the -20 dbm range the outputs of the generators start creating their own IP3 IM products. I can readily measure IP3 of +18.75 dbm (pushing the -30 dbm range to +3 or -27 dbm, and taking into account the 6 db loss I have in the splitter I use to combine the two generators).

In addition the signal generator need to be really, really clean or the noise skirts of the generator signal will start swamping the receiver. A HP8640b is pretty clean.

In my case, for a NC30, an IP3 of +18.75 dbm means two signals of strength -33 dbm each, creating an IP3 spur of -136.5 dbm when the two carriers are placed 5 and 10 KHz lower than the received frequency. Again, +19 dbm IP3 would not lead you to believe that two signals of -33 dbm would be capable of producing a receiver spur.

You might well be able to build one, but I have several made by H-P
which are beautiful little units with greater accuracy and sensitivity
than you could ever hope to make on your own. Frequencys up to 525MHz
are available, but price goes up with frequency, from $50 to $120.

Email me if you are interested in specifics.

That's correct - IP3 is not a power *handling* level. The higher the
figure, the more obvious this becomes!

>This is not to minimize the fact that an IP3 of +40 dbm is pretty good,

>not obvious that two signals at -18.3 dbm could create a receiver spur
>in a radio with an IP3 of +40 dbm.
>
Perhaps the best way to use IP3 figures is to note that most commercial
rigs don't manage more than the low +20s. So a +40dBm figure gives you
about
(2/3)*(40 - 20something) = 10-12dB more "headroom" in the signal levels
it can handle without noticeable IMD.

G3RZP wrote an interesting article in QEX for May/June 2002 reporting
measurements of strong signal levels around the 40m band in Europe (the
worst case he could find), and then worked out the IP3 performance
required to prevent IMD appearing in the amateur band.

At many times of day you might theoretically need an IP3 in the low to
mid +30s - but that is in order to prevent IMD appearing above the
receiver's MDS. The rigs with IP3s in the low +20s survive because the
IMD is masked by the "atmospheric" noise on the lower bands.

Equally important is the IMD between strong amateur signals, close to
the weak one you want to hear. Rigs like the K2 and CDG2000 preserve
their good IMD performance close-in, because they convert straight to a
narrow IF filter. That's where they score heavily over the commercial
rigs that up-convert to a wide first IF (typically 10-20kHz) - inside
this bandwidth, IP3 often degrades to about *minus* 20dBm.

Two nights of CQWW CW on 40m have just reminded me of this! With a typical +20dBm commercial rig, there was just the odd trace of BC IMD here and there in the bottom end; not strong enough to cause any trouble in practice. But the close-in IMD between the biggest CW signals sometimes made it hard going.

G3RZP also noted the value of an input attenuator, which effectively shifts the whole dynamic range upward. This helps both the BC and close-in IMD. Unfortunately the single 20dB step available in most mid-price rigs is way too big (wonder why - maybe it's the right value in JA?). I've modified both my rigs to 10dB, which reduces the IMD by 20dB without making the receiver too deaf, so works out pretty well in practice; but much finer steps would be desirable.

>It is really, really hard to measure +40 IP3!

Fortunately the CDG2000 measurements have been repeated by "Our Mutual Friend" in the USA, so the claimed performance is genuine.

If +40 dbm does not mean 40 db above one milliwatt then why is the added and not just *40 db ? YOu have to refferance a db to something to have any meaning and normally the small m means one milliwatt.

If they want to use one generator at -130 dbm and another + 40 db from that , do not use +40 dbm, just use +40 db or -90 dbm.

It's a fact -- dBm is an absolute power measurement. 0 dBm = 1 mW. 30 dB above that, +30 dBm = 1 watt. 10 dB above that is +40 dBm, which is and always has been just another way to say 10 watts.

I agree with Ralph; sounds like the rx measurement in question should be in dB, which is just a relative measurement.

I have seen this parameter listed at levels as high as +70 dBm -- totally ridiculous. Why is this parameter measured in dBm?

Source record: 39762

Another way of measuring IP3, as stated in the Mini-Circuits RF/IF Designer's Handbook is to use the formula,
IP3 = (P + A/2), where P is the combined power coming out of the two RF generators, and A is the spread between the desired tone and the IM sidebands. To do this properly, you really need to have some sort of isolation between the two RF sources, either by using attenuators or circulators. In order to override these system losses, you will need some sort of linear amplifier at the output of each of the RF generators. Finally, the combined RF power at the mixer input must be below the compression point of the mixer. For a Level 7 mixer, -20dBm would be an ok level. With some of the Mini-Circuits mixers, they would start to compress at -10 to -15dBm. I remember trying to characterize some of these mixers for SSB conversion loss, and didn't understand why the measured loss was higher than the manufacturer's stated loss.
Another interesting thing that I ran into when I was making some desense measurements on a narrowband system. The desired signal was at -140dBm, while the interfering signal level was varied, depending on frequency separation. The interesting thing was that, even with a 400MHz spread, there was enough broadband noise from the signal sources (8640Bs and 8642Bs) that I had to use some sort of tunable filter at the output of each generator. I had never realized before this point at time that the noise could be that far removed from the fundamental output of the RF generator. Finally, I didn't mention this alternate technique to minimize Mr.Tayloe's method; I think that the method that I use to characterize IP3 might be more of a "quick and dirty" approach. Thanks to you, Mr. Tayloe, for the insight that you provide to this group!

Pete KE9OA

4050. Re: K2 Owners

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-11-25 00:03:12 UTC

Source record: 39763

IP3 is a mathematical concept. The term is called "third order intercept". IP3 spurs rise 3 db for every one db increase in the two off frequency, high level signals. At such a rate, the spur should eventually catch up in size with the interfering signals themselves. This "crossing condition" is what IP3 describes.

IP3 indicates this "crossing point". However, what we as hams what to know is what kind of signals can my receiver tolerate before I get spurious signals in my receiver. This is an entirely different question.

Rather than talk about IP3, which gives no real feel of the actual size of the signals that will cause MDS IP3 spurs, I think that IP3 dynamic range (or "spurious free dynamic range") is a better measure. This gives the span from the MDS (minimum discernible signal) of the receiver to the signal level that will cause IP3 spurs at an MDS level. If you tell me that my receiver has a IP3DR of 100 db, and that my sensitivity (MDS) is -135 dbm, then I know that I will get spurious responses in my receiver if the off frequency signals get above -35 dbm (100 - 135).

Although IP3DR seems to be a more usable number, it also does not tell the entire story. IP3 is usually measured with two strong signals at 20 and 40 KHz away from the desired frequency, producing a IP3 spur on frequency. However, in a contest situation, the "big guns" are usually up close an personal, and not 20 and 40 KHz away.

I like the ARRL swept IP3 dynamic range measurement, since it shows how resilient a receiver is to big signals close in. It is much, much easier to get a good IP3DR rating at 20 and 40 KHz away (or at 50 and 100 KHz away as some manufacturers rate their stuff), than it is to get a good rating at only 2 and 4 KHz away. The IP3 performance of all receivers get worse as the signals get close in. However, some receivers get worse a lot faster than others.

I know what a K2 does close in with IP3. It would be nice to hear how the CDG2000 performs close in as well.

The close in IP3 tests better reflect contest or DX pileup conditions. It is hard to work weak stations if it is buried in a roar of high level IP3 spurs.

Sorry folks, I made a mistake on that last formula. P should have been stated as the combined power of the two RF Generators at the RF input port of the DUT, not the combined power coming out of the generators themselves. There are test setup losses that need to be subtracted as a Calibration Factor. Must be late in the day!

IP3 is an *absolute* power level, so dBm is correct.

On the other hand, the so-called "intermodulation-free dynamic range" is *relative* to the receiver's noise floor. Both ends of the dynamic range are absolute power levels measured in dBm, so the difference is in plain dB.

>I have seen this parameter listed at levels as high as +70 dBm --
>totally ridiculous.

Not today - the cellular industry is crazy about low intermod levels (because it creates QRM between channels) so everything gets characterized. Component such as connectors cause "almost no" IMD, so they have these very high IP3 levels... which, as Dan said, are a pig to measure.

>Why is this parameter measured in dBm?
>
Industry standard.

Tnx, Dan, for your explanation of "IP3".

I remember when DeMaw was doing the heavy lifting on RX performance measurements. If I recall correctly, he was the one who picked the 20 & 40 KHZ spacings. I agree that they do not represent real world operating conditions. My theory has always been that RX's in DeMaw's time were so poor that he had to use 20/40 to get reasonable numbers! :-)

But the current reality is different. Amplifiers and systems are better, signal sources are loaded with phase noise, limiting their usefulness, and we are stating theoretical results (IP3) in units that make no sense in the real world. Is there a movement to change this situation? Maybe use clean analog oscillators? Measure a different parameter than IP3? Is the ARRL on board with this, or are they sticking to DeMaw's system?

Again, tnx.

That is one of the good things about a single conversion receiver, but it doesn't have much to do with whether the design is upconversion or not. The upconversion topology used in a dual or triple conversion receiver isn't the limiting factor, as much as the reciprocal mixing that can occur at the 2nd mixer and/or 3rd mixers in a multiple conversion system. Because the roofing filter at the 1st I.F. is approximately 15kHz wide, there is more signal power appearing at the 2nd mixer than if a 2.4kHz filter were used. The maximum system bandwidth is defined by the first selective filter in the signal chain; by using a narrow roofing filter, close-in IM performance will be better than if a wider filter were used. If the LO had no noise sidebands, this wouldn't be an issue. A couple of ways to improve the synthesizer are to use a very narrow crystal filter at the output of the reference oscillator to clean up its sidebands, and to use a Modulated Fractional N Divider. With an MFD type of synthesizer, close-in phase noise is very low, because the noise is translated out several hundred kHz.

I should have read the thread more carefully. That calculated IP3 is just that, a calculated value and not what the receiver is really hit with. It is only a calculated point from two differant slopes converging. I never did like the calculated values if you can not reach them or if the device will not take it to prove the calculations work.

Maybe the IP3 numbers don't fit your idea of a meaningful number, but it is a useful number, one of several. A receiver with a good IP3 number is a whole bunch more pleasant to operate than one with a crummy IP3. Maybe it isn't easy to intuit what it should be from the number and no experience, but it is still a good, useful, number. And when coupled with just a little bit of experience, it tells a whole lot about a receiver. Not everything, the other measurements mean something, too.

Of course we can come up with better numbers, but one problem with 'better' is that, by definition, it's different. Until someone like ARS does the 'better' test on a whole range of rigs, it's usefulness is pretty limited.

Do not get me wrong. I like what the ARRL has done in performing swept IP3 dynamic range measurements. These graphs go a long way in showing what happens with strong, off frequency signals both far out and close up.

If I could change anything, in addition to the wide range swept IP3 dynamic range charts (+/- 100 Khz range?), I would like to see a separate chart that zoomed in and focused on the IP3 dynamic range performance at +/- 10 KHz and less. Although the further out spacings are important, the real world benefit in IP3 performance is in this "close in" range. If receivers can handle the close in stuff, the far out stuff will not be a problem.

In the North American version the IC-32AT there was a reset function
you could do to toggle 5 and 12.5 kHz tuning steps. I am not sure if
the European version can do the same.

In most cases Icom uses different cpu's or cpu diode matrixes for
their different versions. I once changed a W2A from European to North
American version and it did require the installation of two new cpu's.

The IP3 figures are easily comparable (provided that you can agree on if you are talking about input or output IP3 :-). You can also calculate the absolute level of the spur and relate it to the band noise (not just receiver noise).

The problem with this definition is that it contains the definition of the MDS, which depends of the receiver noise bandwidth (which could vary from several kHz for phone communication to 0.001 Hz for QRSS operation). Thus, both the IP3DR and MDS must be given in order to be able to make any real comparisons. To scale the figures to other bandwidths, you have to know the bandwidth used when measuring the MDS.

In my opinion, the IP3 and (the receiver noise figure from which the antenna temperature, noise power density and MDS for any given bandwidth can be calculated) will give the best picture of the receiver performance as long as you can agree on if you are talking about input or output IP3.

The RadCom reviews by G3SJX have been doing this for well over 10 years, always presenting the results in the same way so there's a good database of comparable measurements. DL1BU's measurements for CQ-DL are comparable.

As well as table of close-in IMD performance at 7MHz (down to 3kHz spacing), G3SJX presents a composite graph of "effective selectivity" out to +/-30kHz. In the center is the IF filter curve, but rejection of very strong signals on the skirts of the passband is effectively limited by front-end performance, either oscillator sideband noise or two-tone IMD.

For a conventional rig with a 20-30kHz roofing filter, you can very clearly see how the close-in IMD performance deteriorates inside that filter's passband.

There are no published detailed figures (but you may be able to get them
from HJ).

The design notes state that overall input IP3 is about +40dBm, except close-in. The mixer IP3 is 36-39dBm, and the loss of the bandswitched input filters is added to this to give the overall IP3.

Noise floor in 2.2kHz bandwidh is -127dBm (worst case) so the IFDR is (40 + 127)*2/3 = 111dB.

That simple analysis breaks down close-in, because "the IM3 of the post mixer amplifier is only +13 dBm. Hence close in, IM3 is degraded so that when the roofing filters offer less than 25 dB attenuation, the post mixer amplifier will dominate performance. This occurs closer in than . Signals this close in, but outside the quality filters, either SSB or CW, will suffer degraded IM3."

More details should be calculable from the detailed performance figures, which are at www.warc.org.uk

The close-in IMD problem is essentially solved for SSM, because the roofing filter is almost as narrow as the main "quality" IF filter. Receiver IMD is likely to be lost under the transmitted IMD.

For CW, the clo-in IMD is a huge improvement over the up-converting receivers with 10-20kHz roofing filters. The performance only degrades closer than +2 and -3.2 kHz, and that kind of performance limitation must be true in a similar way for the K2 and any other transceiver with a similar front-end. If you're really, really serious about CW, you'd use a narrower roofing filter for that mode... but then you're still limited by phase noise and key clicks (always other people's, of course).

It would be interesting to have both the CDG2000 and the K2 on the ARRL lab bench - and ultimately more important, on the operating bench.

>The close in IP3 tests better reflect contest or DX pileup conditions.
>It is hard to work weak stations if it is buried in a roar of high
>level IP3 spurs.
>
I can still hear them from last night... In reality a CW contest pileup is limited by on-frequency signals, because stations don't

operate significantly split. A worse situation is a CW DXpedition pileup where a weak station is operating "UP1", so the 3rd-order IMD from the pileup 1-2kHz away lands exactly you-know-where.

On the subject of Tayloe detectors, correspondents might be interested in my experiences with my own receiver which uses a Tayloe detector with 4-path audio polyphase network:
http://www.hanssummers.com/radio/polyphase/index.htm. Currently it is only for 80m but plans are afoot to make it multiband.

This page doesn't yet contain complete details, because the receiver is still under construction. The photos come from various stages of development so some are out of date. In particular, the "main" board is now sawn up and the RF sections placed in PCB-shielded modules. I lowered the gain of the pre-polyphase network amplifiers from 33dB to 24dB because I was worried about overloading (perhaps unnecessarily). I rebuilt the Tayloe detector and divide-by-4 more neatly and in a shielded enclosure. I repaired the clock in the top left of the front panel (previously the LED displays suffered melting damage due to overheating due to too low multiplex duty cycle). Both the frequency counter and the clock have On/Off switches in case I am paranoid about digital noise, but so far the noise levels aren't affected whether the units are On or Off.

This is my first ever rig, I have never owned a commercial station. I had my first QSO ever with it in March this year and have now had 130 QSO's with 16 countries from here in the UK, on 80m in conjunction with my one valve 10W tx http://www.hanssummers.com/radio/cwtx/index.htm. Usually I set the power to 4 or 5W, and many of my QSO's even with Sweden, Poland etc are 2-way QRP.

(One complaint about the contesters. Was enjoying a nice 2-way QRP QSO on Friday night with Carl SM6USL when the contest started at midnight, and suddenly there were QRO QRQ contesters all over us, so much QRP we couldn't even 73. I couldn't get a word in edgeways for the rest of the weekend

except some intra-G daytime Sunday...)

Whilst I have nothing to compare it with, and have no measurement equipment to determine performance, I think my receiver using the Tayloe detector sounds excellent.

I am not sure if the CPU is still available. I no longer work for
Icom America. The CPU is smd technology and is soldered to the logic
board.

If you have a schematic you could try changing the diode matrix to
match the North American version or U.S.A. version. I don't remember
how the schematic is labeled.

I ran a lot of experiments when designing that rig, and (as reported in the QST article) found that good quality NPO capacitors were the most reliably temperature stable. Some people have reported poor drift performance with NPOs of unknown parentage, but solved the problem by purchasing new ones from a reputable vendor. I've never seen the poor drift performance with any I've used.

I agree about silver mica capacitors. The stability (and Q) varies from part to part.

Polystyrene capacitors have a moderate but pretty predictable temperature coefficient. It turns out to be in the opposite direction from most inductors, but it's considerably higher than a decent inductor like the one used in the Optimized rig. From time to time someone designs (and publishes) a VFO designed with a rather poor inductor and a polystyrene capacitor that fortuitously match more or less in drift, accidentally resulting in decent performance. That's probably how polystyrene capacitors got the reputation of having lower drift than they really do. Needless to say, builders attempting to copy such a design are often disappointed by the drift. Trying to compensate a large error with an opposing large error is poor design practice that nearly always leads to grief.

The VFO in the Optimized rig typically drifts about 200 Hz from turn on at 40 meters without any temperature compensation. This drift can be reduced if desired by replacing a portion of the NPO capacitance with negative temperature coefficient parts.

Thank you for the URL's.

I was made aware of Millers who I have just contacted.

Gowanda are represented here in the UK but not sure if they offer what
I'm after - plate chokes.

Fastron look OK.

Your amp has come on since it conception a couple of years back. I
remember all the grief you received on the CB ng. Good looking indeed.

Now all you need to do now is add six more 2879's, a switchable low pass
filter and forget about your home market where of course you have to
by-pass 10/11m.

I have two Metron amp's which equate to what you need. Shame they
haven't made them in nearly a decade.

4071. Rock-Mite question

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-11-25 23:53:33 UTC
From: "Joe S." <joe@schlatter.org>
Message-ID: <arud2t01qrp@enews1.newsguy.com>
Source record: 39785

What do you Rock-Mite users out there use for batteries?

I have built a 40-meter RM and will put it in a box tonight. I have an Altoids box drilled and ready to go but I also have two of the beautiful anodized boxes from American Morse -- don't know which box to use.

I want to keep the battery size as small as possible. It seems that the options are:

-- eight AAA batteries; 12VDC but how long would they last?
-- eight AA batteries, 12VDC, bigger than AAA's, how long will these last?
-- two 9-volt batteries in series with something to drop voltage to 12 - 14 VDC; but how long would these last?
-- I found a sealed gel-cell, 12VDC, 1.3 A-Hr battery - but - it's the size of three Altoids boxes stacked; would probably last forever.

Also, what do you RM users recommend -- alkalines? Ni-Cads? NiMH?

Thanks for the assistance.

It's always interesting to hear results obtained from those who've
tried something new!

One of the points I wanted to highlight originally was the effect of
strong near-frequency signals on direct-conversion receivers. As an
example, let's assume a strong signal is received at a level of -70
dbm (70.7 uV). An even stronger signal exists at -30 dbm just a
few KHz away. It is at a level of 7.07 mV at the antenna.

The NorCal 30 has an audio preamplifier stage with a voltage gain
of 100 to 200 (depending on source resistance equivalent of the
multiplexer-mixer). The example's strong signal winds up at 0.707
to 1.414 V out of the preamp or 1.0 to 2.0 V peak. If that strong
signal is frequency-separated by, say 4 KHz, it is within the
response region of the preamp (as far as I can tell from the
PacifiCon exhibit schematic). That's terribly close to the supply
rail level of +3 VDC and is at or very near limiting/clipping.

The examples I gave are not rare insofar as signal levels can go.
I've had stronger interfering signals from a ham station a few
blocks away. The example levels aren't within the IP3
intermodulation conditions of the mixer at all but they can effect
interference on a desired signal past the mixer. One saving
grace is that on-off keying desired signals may be less affected

by clipping/limiting at CW compared to SSB voice but they
should definitely be noticed.

One possible cure is passive lowpass filtering directly between
the mixer and any audio amplifier, but that adds bulk. Another
is increasing the supply rail voltage to increase the post-mixing
audio dynamic range. Yet another possibility is combining the
bandpass filtering as part of the preamplifier stage.

Out of curiosity, are you using a Gingell polyphase network or
another type? The common Gingell circuits have an inherent
bandpass characteristic in addition to relative quadrature phase
shifting.

Continued success on your homebrewing!

<< I looking to build a reference oscillator, but it need
only be within a Mhz or two of 135 MHz, so I'm wondering
if I can use a cheap microprocessor xtal. >>

Russ-

The exact frequency may not be important, but what about stability? Microcomputers usually don't have a stringent clock frequency requirement, but what about your application?

Another question, do you intend for your oscillator to operate at 135 MHz? Crystals oscillate in overtone mode at odd harmonics, but you'll seldom find one working any higher than the fifth harmonic, with third being more common. Further, higher frequency crystals (such as for a 27 MHz fundamental) are going to be extremely fragile and susceptable to being fractured by excessive drive.

A more practical approach might be to have your crystal oscillate at a lower frequency such as 9 MHz fundamental mode or 27 MHz third overtone (from a CB Set?), and follow the oscillator by a 5X frequency multiplier stage (or two 3X stages?). Depending on output level requirements, additional gain stages may be needed.

Len's suggestion of using a PLL is a very good one. If stability is needed, you can use an oven-controlled oscillator at a lower frequency, and phase lock a 135 MHz VCO to it. Even without the oven, it is likely to be more stable and reliable than a crystal oscillator oscillating at 135 MHz.

<< why can't i mod the siltronix
vfo for the ham bands >>

KU4YP-

Do you know what company made the Siltronix? I understand it was a company like Swan that didn't want their name associated with CB!

If it is that simple, you may find that the VFO is internally identical to one of the other company's Ham VFOs. Adding a band switch and a few other components might make the conversion complete.

I would guess the VFO currently works at one quarter or one third of 27 MHz (6.75 or 9 MHz), and may be the same as the equivalent Ham VFO's 11 Meter circuit which might have existed prior to about 1958. If it is at 9 MHz, you can probably pad it down to cover the 7 MHz band, which would also handle the harmonically related bands (14, 21, 28 MHz).

This wouldn't help at 3.5 MHz, so a second circuit is needed. As you can see, it is getting complicated. Perhaps another look at E-Bay is in order!

As usual, I found the article when I wasn't looking for it.

It is the September 1946 article.

The article does mention the US patent for the pulse counting detector, number 2,137,859 issued to W.W. Moe and assigned to General Electric. I didn't check the patent, but I think it's just the actual detector, while the article is about a complete receiver by the inventor. There is no complete schematic; only the segment which is the 200KC final RC-coupled IF amplifier and limiter, and the actual pulse counting detector, a 6H6. It's mainly about the detector scheme, with a block diagram and a small description of the complete receiver.

It mentions that the inventor, who was W1JKC at the time of publication, worked for GE between 1935 and 1945, as a radio receiver engineer, doing "design work on the well-known JFM-90 FM translator", while during the war working on naval radar equipment. After the war was over he worked on TV receiver design.

I wonder how much this impacted on later designs. In the GE semiconductor manual from the early sixties, there is a simple FM broadcast receiver consisting of a tunnel diode mixer/oscillator stage, and a 200KHz RC-coupled transistor amplifier/limiter stage, followed by a pulse-counting detector. Then about 1976, I saw some simple FM broadcast receiver designs in a British magazine that directly dropped to such a low IF. There's nothing to stop someone coming up with such a scheme independently, but I'm always curious about whether something is being done because it's been done already.

Your Rockmite should function on 9v.

Try two 9v batteries in parallel for a long lasting supply of electron flow.

That's interesting. I am using a 12V supply for my op-amps between the mixer
and the polyphase network. I used to use a voltage gain of 47 in these
opamps, but I recently reduced it to 15 because I was worried that strong
signals might cause clipping. But too low and the noise of the polyphase
network would become significant... perhaps 15 is too low, do you think?

The trouble is also that anything between the mixer and the polyphase network must be precisely matched in 4 paths for both amplitude and amplitude response with frequency. But as Dan said, the Tayloe detector inherently has a filtering characteristic (that I measured and the results on my page).

>
> Out of curiosity, are you using a Gingell polyphase network or

My network circuit is shown on my webpage http://www.hanssummers.com/radio/polyphase/index.htm, I read about the Gingell network but don't recall exactly if mine is similar. I designed mine using the Nov 1995 QEX article (also reproduced on my page): Polyphase Network Calculation using a Vector Analysis Method, by Tetsuo Yoshida JA1KO. In this design the resistance and capacitance change from column to column, rather than the usual designs which use either constant resistance or constant capacitance. The design ensures constant amplitude response over the whole audio range, i.e. the network is lossless. I also verified this by measurement, the results are on my page.

4085. No more small parts at Radio Shack--Ain't So!!

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-11-26 14:23:50 UTC
From: jim.bolinger@lintek.aeroflex.com
Message-ID: <8d5ec8a2.0211260623.6c0f665e@posting.google.com>
Source record: 39648

There was a thread here a while back talking about the demise of small parts at radio shack.

I was in our local one last night looking for some batteries. It was the first time that I had been there for several months.

As I was expecting, the stuff on the racks was rather limited. Then I turned around and noticed a brand new steel cabinet with 50 or so drawers. Each drawer had a dozen or so compartments full of small parts, all neatly sorted and labeled. My impression was that they had a better assorment than when they used wall racks.

By the way, any physically disabled read this group? If I were you I would be really ticked-off at Radio Shack. With all their Christmas junk piled up even I had trouble getting down the aisle. I can't imagine what problems a wheel chair would have!

Source record: 39650

I am mentally disabled when I go into RatShack on a Sunday afternoon needing
a 7805 or something to find that they are all out of stock.

My nephew brought his son into radio shack to exchange a video tape player.
It seems that this 3 year old son had stuck a peanut butter sandwich in the
cassette drawer. They took it back, somewhat unhappily, but they still
took it back as it was still under warranty.

They must have the same warrenty I read about from another company (might have been MFJ) that says even if a truck runs over it , it will still be covered for a period of time. I just don't see a company covering a product under ovious missuse.

Hello Anyone,

Can anyone give me info on getting sound information form sound card? What I need to get from sound card is Frequency and amplitude of a tone(s), going into the Audio input to the sound card. How is this done with Visual basic 6. Feel free to email me direct. Thanks, Bruce

Its a comfort thing for the buyer and a good marketing tool. Nothing specific, just a warm fuzzy feeling that you won't be hassled over the return.
Of course the buyer pays for that protection and if the item selling price is jacked up 10% as a result, the vendor probably makes a killing since 90% of the buyers won't be returning the item. They know the actuarials of their equipment.
However, it sounds like an admission by the vendor that the unit is as likely to fail on its own as it is because of abuse. Having your kid shove a sandwich into the rig BEFORE it breaks down is no different than it breaking down and THEN shoving a sandwich into it.

4093. High Voltage Transformer

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-11-27 00:02:46 UTC
From: George Clute <glcute@attbi.com>
Message-ID: <dXTE9.4672$GR5.83@rwcrnsc51.ops.asp.att.net>
Source record: 39656

I've carried this thing around for 30 years, and its time to find it a new home.
I ran a couple KW with this transformer and it is solid. Never got warm when running at full tilt. I'm sure the 2.1 KVA 220VAC input is a military spec. In amateur service it would be difficult to hurt this transformer.

Benjamin:

Go to the ARRL site (www.arrl.org) and look for the UHF/Microwave Projects Manual (two volumes) and the VHF Experimenter's Handbook. The experimenter's handbook probably fits your request best. The RSGB also has a 3-volume set with stuff on all the microwave bands, but it's kind of dated by now.

Also check out www.downeastmicrowave.com. They sell kits, boards, etc. and have some general information on interfacing equipment and other details on the site.

I've seen applications where 27MHz xtals have been operated on 9th
overtone (81MHz) to be used for microwave ssb/cw transverters, so I
don't think stability is so bad problem. But, as you mentioned 27MHz,
it is fairly easy to operate the xtal on 45MHz using a Butler
oscillator, with the second tuned circuit to 135MHz.
I've tried it several years ago for a 2m NBFM receiver, but I won't
mention about signal purity. Two stages tuned circuits or more may be
needed on 135MHz to attenuate 45 and 90MHz products

Some fundamental cut crystals do not like to operate on an overtone.
They can sometimes be
quite unstable. It depends on how the particular crystal is cut.
A crystal that is intended to operate as an overtone crystal is cut
differently than a fundamental.
Also the overtone frequency is usually slightly different than the
multiple of the fundamental.

I was interested in the Pegasus for use as a data radio but lost interest when I learned that it takes TWO computers, one to run the radio and the other to communicate. I had thought one might be able to multitask with one.

But you're right- there's something about radio that just doesn't come out right when the control panel is a computer screen and the only knob is a mouse!

Dick

TURN $6 INTO $6,000? READING THIS COULD CHANGE YOUR LIFE!

TURN $6 INTO $6,000? READING THIS COULD CHANGE YOUR LIFE!

A friend of mine alerted me to this opportunity which he came across.
He explained that you send $1.00 to each of the 6 names and address
stated in the article. You then place your own name and address in the
bottom of the list at #6, and post the article in at least 200 newsgroups.
(There are thousands) No catch, that was it. So after thinking it over,
he tried it, figuring he had nothing to lose but 6 stamps and $6.00.

GUESS WHAT!!... Within 7 days, he started getting money in
the mail and the money just kept coming in.

In his first week, he made about $25.00. By the end of the
second week he had made a total of over $1,000.00! and after four weeks
a total of just over $42,000.00 and it's still coming in rapidly.

He hooked me and now I myself am at the 1500.00 level.

It's certainly worth $6.00, and 6 stamps, I have spent more than that on the
lottery!! Let me tell you how this works and most importantly, why it
works....Also, make sure you print a copy of this article NOW, so you can
get the information off of it as you need it. I promise you that if you
follow the directions exactly, that you will start making more money than
you thought possible by doing something so easy!

Suggestion: Read this entire message carefully! (Print it out or download
it.) Follow the simple directions and watch the money come in! It's easy.
It's legal. And, your investment is only $6.00 (Plus postage)

IMPORTANT: This is not a rip-off; it is not indecent; it is not illegal; and
it is virtually no risk - it really works!!!! If all of the following
instructions are adhered to, you will receive extraordinary dividends.

PLEASE NOTE: Please follow these directions EXACTLY, and $50,000 or more can
be yours in 20 to 60 days. This program remains successful because of the
honesty and integrity of the participants. Please continue its success by
carefully adhering to the instructions. You will now become part of the Mail
Order business. In this business your product is not solid and tangible,
it's a service. You are in the business of developing Mailing Lists.
Many large corporations are happy to pay big bucks for quality lists.
However, the money made from the mailing lists is secondary to the income
that is made from people like you and me asking to be included in that list.
Here are the 4 easy steps to success:

STEP 1: Get 6 separate pieces of paper and write the following on each piece of paper; PLEASE PUT ME ON YOUR MAILING LIST. Now get 6 US $1.00 bills and place ONE inside EACH of the 6 pieces of paper so the bill will not be seen through the envelope (to prevent thievery).

Next, place one paper in each of the 6 envelopes and seal them. You should now have 6 sealed envelopes, each with a piece of paper stating the above phrase, your name and address, and a $1.00 bill. What you are doing is creating a service. THIS IS ABSOLUTELY LEGAL! You are requesting a legitimate service and you are paying for it!

U.S. Post Office(1-800-725-2161) confirmed that it is indeed legal! Mail the 6
envelopes to the following addresses:

Mailing Addresses

(1) B. Evans

34580 Seminole way

Solon, OH 44139

(2) S. Paramadilok

3730 Wallen Ave.

Lincolnwood, IL 60712

(3) M. Roberts

1912 Flagler Ct.

Virginia Beach, Va 23464

(4) TJ Ross

305 Briarhill #9

London, ON n5y 4v7

(5) James HU

24 Shilton Road

Toronto, ON, M1S 2J6 Canada

(6) N T Greenidge

2710 Arlington Ave

Bronx NY 10463

STEP 2: Now take the #1 name off the list that you see above, move the other names up (6 becomes 5, 5 becomes 4, etc...) and add YOUR Name as number 6 on the list.

STEP 3: Change anything you need to, but try to keep this article as close to original as possible. Now, post your amended article to at least 200 newsgroups. (I think there are close to 24,000 groups) All you need is 200, but remember, the more you post, the more money you make! This is perfectly legal! If you have any doubts, refer to Title 18 Sec. 1302 & 1341 of the Postal lottery laws.

Keep a copy of these steps for yourself and, whenever you need money, you can use it again, and again.

PLEASE REMEMBER that this program remains successful because of the honesty and integrity of the participants and by their carefully adhering to the directions. Look at it this way. If you are of integrity, the program will continue and the money that so many others have received will come your way.

NOTE: You may want to retain every name and address sent to you, either on a computer or hard copy and keep the notes people send you. This VERIFIES that you are truly providing a service. (Also, it might be a good idea to wrap the $1 bill in dark paper to reduce the risk of mail theft.)

So, as each post is downloaded and the directions carefully followed, six members will be reimbursed for their participation as a List Developer with one dollar each. Your name will move up the list geometrically so that when your name reaches the #1 position you will be receiving thousands of dollars in CASH!!! What an opportunity for only $6.00 ($1.00 for each of the first six people listed above) Send it now, add your own name to the list and you're in business!

---DIRECTIONS ----- FOR HOW TO POST TO NEWSGROUPS----------

Step 1) You do not need to re-type this entire letter to do your own posting. Simply put your cursor at the beginning of this letter and drag your cursor to the bottom of this document, and select 'copy' from the edit menu. This will copy the entire letter into the computer's memory.

Step 2) Open a blank 'notepad' file and place your cursor at the top of the blank page. From the 'edit' menu select 'paste'. This will paste a copy of the letter into notepad so that you can add your name to the list.

Step 3) Save your new notepad file as a .txt file. If you want to do your postings in different settings, you'll always have this file to go back to.

Step 4) Use Netscape or Internet explorer and try searching for various newsgroups (on-line forums, message boards, chat sites, discussions.)

Step 5) Visit these message boards and post this article as a new message by highlighting the text of this letter and selecting paste from the edit menu.

Fill in the Subject, this will be the header that everyone sees as they scroll through the list of postings in a particular group, click the post message button. You're done with your first one! Congratulations...THAT'S IT! All you have to do is jump to different newsgroups and post away, after you get the hang of it, it will take about 30 seconds for each newsgroup!

**REMEMBER, THE MORE NEWSGROUPS YOU POST IN, THE MORE MONEY YOU WILL MAKE!!

BUT YOU HAVE TO POST A MINIMUM OF 200**

That's it! You will begin receiving money from around the world within days!

You may eventually want to rent a P.O. Box due to the large amount of mail you will receive. If you wish to stay anonymous, you can invent a name to use, as long as the postman will deliver it.

JUST MAKE SURE ALL THE ADDRESSES ARE CORRECT.

Now the WHY part: Out of 200 postings, say I receive only 5 replies (a very low example). So then I made $5.00 with my name at #6 on the letter. Now, each of the 5 persons who just sent me $1.00 make the MINIMUM 200 postings, each with my name at #5 and only 5 persons respond to each of the original 5, that is another $25.00 for me, now those 25 each make 200 MINIMUM posts with my name at #4 and only 5 replies each, I will bring in an additional $125.00! Now, those 125 persons turn around and post the MINIMUM 200 with my name at #3 and only receive 5 replies each, I will make an additional $626.00! OK, now here is the fun part, each of those 625 persons post a

MINIMUM 200 letters with my name at #2 and they each only receive 5 replies, that just made me $3,125.00!!! Those 3,125 persons will all deliver this message to 200 newsgroups with my name at #1 and if still 5 persons per 200 newsgroups react I will receive $15,625,00! With an original investment of only $6.00! AMAZING! When your name is no longer on the list, you just take the latest posting in the newsgroups, and send out another $6.00 to names on the list, putting your name at number 6 again. And start posting again. The thing to remember is: do you realize that thousands of people all over the world are joining the internet and reading these articles everyday?, JUST LIKE YOU are now!! So, can you afford $6.00 and see if it really works?? I think so... People have said, "what if the plan is played out and no one

sends you the money? So what! What are the chances of that happening when there are tons of new honest users and new honest people who are joining the Internet and newsgroups everyday and are willing to give it a try? Estimates are at 20,000 to 50,000 new users, every day, with thousands of those joining
the actual Internet.

IMPORTANT: When you send the six envelopes out, you create a service, a LEGAL SERVICE.

Remember: Play FAIRLY and HONESTLY and this will really work!!!

Happy Holidays and Good luck, Good health and wealth.

4106. Re: HF PA project wanted

What I have is a commercial amplifier, Gonset GSB-101 that has been converted from four 811A tubes to four 572B tubes. The plate transformer has been replaced with a more suitable, larger one, and a few other changes made. There is no filter capacitor but I have all the parts, new ones, to build up a proper filter with a series string of electrolytic capacitors and equalizing resistors. This should end up as a full legal limit amplifier from 10-80 meters full coverage (yes it tunes the WARC bands).

I never finished the project because I got two other amplifiers. It's just sitting here taking up space and I'd like to sell or trade it for something I can use.

I don't know about a list, but if someone wants to start one, I offer
US 2,695,988, "Mixer-Modulator," for consideration. It's a
double-balanced diode ring mixer, from 1954. It may be
the first patented use of the ring, rather than the diode bridge which
had been patented earlier.

(It was one of my uncle's many patents...I was sure impressed when I
saw it in his binder!)

Cheers,
Tom

>network would become significant... perhaps 15 is too low, do you think?

Apologies for not inspecting your website until today...Outstanding!
:-)
I didn't get a chance to check out the NE5534 op-amp specs for
noise, but since those are between multiplexer and the polyphase,
the would be suspect first. The passive polyphase network should
not introduce any noise so one has to look at the voltage-follower
OP27s for noise injection.

As to strong adjacent-frequency signals slamming in at 30 db or
better above desired signal, those can be approximated at each
listening location, measured approximately with a conventional
receiver, then relative strengths calculated as to possible
clipping/limiting effects. The higher the supply rail magnitude,
the wider the dynamic range before limiting occurs...that is a
trade-off thing when it comes to portable QRP rigs.

There's not yet any answer to limiting which will be optimum for
each and every situation.

>The trouble is also that anything between the mixer and the polyphase
>network must be precisely matched in 4 paths for both amplitude and
>amplitude response with frequency. But as Dan said, the Tayloe detector

>inherently has a filtering characteristic (that I measured and the results
>on my page).

Agreed, but the preamps (NE5534s in yours) can be gain-matched
within 1% without trimmers using +/- 1% fixed resistors. Any
differential phase shifts between the preamps should be nil at audio
frequencies on out to 20 KHz. That would leave only magnitude
unbalance as a possible problem for "USB/LSB" rejection. That's
a vector calculation problem to maintain both magnitude and phase
where they should be. That "upper/lower" rejection would be as
upset following the polyphase network as before it...adder and
subtracter arms following the polyphase have to be as balanced.

The FST3255 quad multiplexer is not supposed to introduce any
noise (quote-unquote). Worst-case differential resistance would
be about 10 Ohms? [maximum on or closed resistance spec
sheet value is 15 Ohms] There are probably some switching
transients due to capacitive coupling within the multiplexer and
with the possibility of some slight time skew of the two phases
(digital) out of the 74HCT163. Any time skew there would have
some effect (albeit very small) of possibly unbalancing the
quadrature-equivalent switching...and thus a slight phase un-
balance of the mixer output. That may not seem much af first
but 1 degree at 14 MHz is 198 picoSeconds (or 0.198 nanoSec
for those who don't live near Pico Boulevard...inside joke)...
0.794 nSec at 3.5 MHz.

The demodulator response of the Tayloe mixer is chiefly
governed by RF source resistance plus series resistance
to the multiplexer arm input and the capacitors at each
arm output (330 pFd?) in shunt with the series resistance
of each preamp input (1 K). That can be tailored to fit a
Tayloe... :-)

>My network circuit is shown on my webpage

>In this design the resistance and capacitance change from column to column,
>rather than the usual designs which use either constant resistance or
>constant capacitance. The design ensures constant amplitude response over
>the whole audio range, i.e. the network is lossless. I also verified this by
>measurement, the results are on my page.

I did a response analysis of your polyphase circuit using 10 Ohm
source resistance and 10 to 22 MegOhm output resistance (to
simulate the voltage-followers). My analysis program uses double
precision with phase read-out to 0.01 degree resolution, answer
rounded-off to nearest hundredth. There was NO ERROR of 90
degree differential shift found between 10 Hz to 100 KHz at any
of the outputs! Voltage amplitude is within +/- 1 db from 100 Hz

to 10 KHz! 3 db drop-offs occur at 25 Hz and 25 KHz. I was very much surprised, to say the least.

The Tayloe multiplexer-mixer ought to make one excellent SSB detector with the Yoshida-value polyphase network. With a locked-on-carrier-frequency switch frequency of the multiplexer it would be a good DSB AM detector. I can see all sorts of possibilities there as any AM or carrier detector.

The multiplexer switching input time skew is, by analysis, somewhat "smoothed out" by the Gingell-Yoshida polyphase network. In sweeping 100 Hz to 10 KHz with one source deliberately offset in phase by 1 degree, the four outputs have relative quadrature errors within a +/- 0.23 degree with only a few frequencies bumping to +/- 1.1 degree. The RF switching phase relationship is still a part of the overall error. The nicety of the polyphase network with four quadrature phase input (or even just two as in Peter Martinez' example in Radio Communication in Pat Hawker's column about 1974) is that input phase skew is less of a problem over the passband.

So true, you are dealing with a different species in small children
and they do not respond at all to logic, consequences, instructions -
you just have to put up with this sort of stuff. My exception is my
workshop - I ALWAYS keep it locked, and they are under severe death
threats if they go in there unsupervised.

As a working service tech, if you see a harrassed young parent walking
up the path with a 3 yo in tow, and a VCR under her arm, its almost a
certainty that SOMETHING has been stuffed into the tape flap - the
other thing is kiddies tapes fouling the video heads - they get played
so many times they are very worn and shed oxide.

Just part of being a parent, there is no rational excuse or
justification for being one, its just the way it is.

Andrew

Shudder. Direct hardware access is horse-and-buggy stuff.

Modern operating systems provide sane interfaces, and
don't restrict you to specific models of sound card.
Look in your manual under "sound card" or "multi media".

The poster's original question is actually quite a hard
problem (What if the input isn't a sine wave? What do
you do about noise?). Hence all the work on spectral
estimation and similar pastimes. There is a particularly
good discussion in Numerical Recipes in C.

Or maybe they just need to learn how to move fragile equipment up out
of the reach of their little terrors. Nothing that could harm small
children or be harmed by them should be left where they can reach it.
Safety locks on all of the cabinets with soap and bleach, and all
glass and electronics on the upper shelves. We learned that early with
our four children, and are trying to teach our grandchildren's parents
the same lessons without the same (expensive) consequences we dealt
with.

After the Thanksgiving break, you might want to email the guys at
www.ghz.com. The J0 is a very old series of transistors. If anyone
would know of a replacement, these guys would.

Cheers,
Mike

Cant disagree with any of that Bob, BUT unless you practice 24hr vigilance the cunning little devils will find a way to get past your guard - and in spite of everything you do, it will happen!. My fantasy of the child proof home is tiled walls to adult head height, a stainless steel floor sloping to a central drain, and everything in the room automatically retracts into the ceiling when any animate object under 3ft high enters the area!

But seriously, you do all the kiddy safe things you can think of, but small (and hopefully not serious) accidents will happen.

PS - we are grandparents, so know most of the tricks, but even know still get caught - like, "wheres the remote control...."

4119. Re: Using fundamental xtals for overtones

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-11-28 22:09:58 UTC
From: Rick Karlquist <richard@karlquist.remove.this.com>
Message-ID: <WuwF9.168035$QZ.27742@sccrnsc02>
Source record: 39682

My experience has been that most crystals will happily
work at various overtones (in the right circuit) even if
sold as "fundamental". In fact, accidental operation on
the 3rd overtone is a common problem in microprocessor
clock circuits using a compromise design. The main thing
you get when you buy an overtone crystal is that the frequency
calibration will be correct at the specified overtone. It
won't necessarily be exactly a multiple of the fundamental.
The main issue with overtone oscillation is getting the
right CIRCUIT design. Here's the 2 minute drill. First
build a non-crystal controlled Colpitts oscillator on the
frequency you want. Insert a 22 to 47 ohm resistor in
series with the emitter and if necessary readjust the oscillator
for proper operation. Now replace the resistor with the
crystal. That's it, I've designed 100's of them that way.

If it is that bad I would call their local fire department and
suggest a visit. It is probably in violation of local laws, and someone
could get hurt. Also if there was a fire, they couldn't get very far
inside to fight it with piles of burning paper and plastic so close
together.

Can anyone help me with the schematic for the option KEYBOARD OPERATED SEND unit (KOS-100) for a Doventron MCP-1000C? I know that it is not possible to order that option from Doventron, because Hank Sharfe W6SKC vent silent key in april. The company Web page is altso gone. So if anyone can help me with a scematic so i can build that option, it will be wery nice. Similar circuits tha are easy to build and attach to my doventron will altso be great.

The poster didn't say whether he's looking for powdered iron or ferrite.
Most of the Amidon ferrite cores come from Fair-Rite, which also has a
web site.

4128. Mast Guying query

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-11-29 11:34:13 UTC
From: mike@corn2.freeserve.co.uk
Message-ID: <3de747a0.5803980@news.freeserve.net>
Source record: 39691

Hi Folks, I think I've had a good idea to reduce the area needed to guy a mast and I'd like to run it past you lot, if you don't mind, as I'm certainly no structural engineer
(wuce I could'nt evan spell Ingineer, now I are wun ;-)).

Assume a mast 50 foot high with 4 guys at spaced around the mast at 90 degrees and dropping at 30 degrees to the mast.
This means a distance from the base of the mast to the guy anchors of about 30 foot.

Now. If cross braces are placed halfway up the main mast and the guys are now taken from the top of the mast to the end of the cross bracing and then back to the base of the mast, a bit like a standard kite shape. This reduces the mast base to guy anchor distance to nil and covers half the ground area previously covered, but at 25 feet up.

Am I missing something obvious here ?.

thanks Mike W

This will stiffen the mast to keep it from bending (somewhat) but does
nothing to keep it from falling over.

Should work, the military uses this approach on some tall vertials they use.
Bare in mind that the loading on the base and the mid-sections are very
large, if the material used in these areas is not strong enough a rapid
collapse can happen.
This system is known as a "pre-stressed truss" system. Turn-buckles are a a
must, to pre-load the truss wires equally.
The same principal as the "span" wire on a long boomed yagi, except that the
"top" wire is pre-stressed and counter-acted by gravity in that system. A
vertical requires equally spaced, equally loaded wires around it's vertical
axis.

Don't quit your regular job to go into engineering... :)

If you need a visual aid to see the result of this, just use a six foot wooden dowel
for the mast, several small wood sticks for the cross braces and some scrap wire
for guys.

Glad you liked the page. The top part of it had been corrupted but I've now fixed the file. I chose both the NE5534 and the OP27 for the combination of low noise whilst still not horrendously expensive. The NE5534 is 4nV (per sqrt Hz), and the OP27 3nV. The OP27 is more expensive than the NE5534, but it has an FET input with resistance of 3G as opposed to the NE5534 bipolar input at 100K. This is important for the signals coming out of the polyphase network, since the last column of the network has resistor values of 562K. I

thought the polyphase network would generate thermal noise? How do you calculate how much?

> subtracter arms following the polyphase have to be as balanced.

In the polyphase network I have NO addition or subtraction after the network (see circuit diagram at http://www.hanssummers.com/radio/polyphase/index.htm). In the polyphase design it isn't necessary, you can just take the output from one row. The opposite sideband cancellation occurs within the passive network not in summer/subtracters after the network. The outputs are 0, 0, 180 and 180. Therefore I *could* use them all but I am unsure whether doing so would increase or decrease noise and imbalance, so currently I am just taking one output and it works fine. This is another advantage of 4-phase passive networks vs the I-Q active opamp phase shifting.

Another factor affecting balance is the capacitors in the detector themselves. It is often overlooked but I believe these should also be as closely matched as possible. This is because they have a capacitance dependent amplitude response vs frequency, so even if adjustment pots are used to match the amplitude at one frequency, an inbalance would occur at

other frequencies. So far I haven't tried to match mine yet, but the opposite sideband is still very invisible.

> 0.794 nSec at 3.5 MHz.

Last weekend I rebuilt the detector section of my receiver in a PCB-material soldered together box. There are separate screened compartments for the polyphase network, '163 divider, 3253 multiplexer and switching sections. There will be 5 miniature relays in the "switching section" one of which selects USB/LSB, the other 4 reverse the signal direction turning the detector into an SSB modulator. See this rx will become a tcvr one day.

In the rebuild I used both sections of the 3253 dual 4:1 multiplexer in parallel, to halve the ON resistance. I also used a 74ACT163 instead of the 73HCT163, the ACT is faster. The wires are all very short. I'll take a photo in the next week or so, you'll like it. I used nice decoupling of +5V supply with chokes and capacitors in each compartment, and the +5V regulator in the shielded box too. Connections to the box are via feedthrough capacitors for the DC, and F-type satellite coax connectors for the RF, VFO and AF.

>

Agreed. That's why I am thinking the capacitors should be carefully matched. This time, I also matched the 1K resistors to within 0.1% by putting them in an RC oscillator circuit and adding parallel resistance until the frequencies were the same. What I ended up with was 1K, 1K // 68K // 330K, 1K // 120K // 620K, 1K // 82K // 470K. Next time I will just by the expensive 0.1% resistors rather than this hassle.

> Communication in Pat Hawker's column about 1974) is that
> input phase skew is less of a problem over the passband.

That's very interesting. The 4-path polyphase network is also (I have read)
somewhat more tolerant of component tolerances than 2-path IQ active opamp
phase shifting. The improvement in sideband suppression for comparable
networks is said to be something like 20dB. But, the polyphase network is
lossy, leading to more amplification requirement and thereby noise - until,
that is, Yoshida's version which is loss free over the audio band. In my

opinion this is an excellent receiver configuration.

I have just been given a small quantity of Pye Capacitors. The following
appears on them
RED 220uf
350VDC WKG
Plain Con Neg
EP-203-S
Feb-75-3
Has anybody any data on them, please which might give the ripple current??
Thanks.

>Andrew VK3BFA

Hi Andrew,

I would not classify the sandwich in the VCR as an accident, but negligence. Even the most basic child proofing measures would have prevented it. Think about it: the kid knows that when mom or dad puts something in that slot the TV shows a lot of pretty pictures. He just wants to see what pictures come out of his sandwich. It's all very logical and very predictible. The mandatory Parenting 101 course should teach them to move the VCR (dvd, computer, etc.) out of his reach before he tries that experiment.

Once the basic preventive measures have been taken, the parents should be able to relax their vigilance just a little bit while at home. But if they don't take those first steps, they will spend all of their time chasing the kid and they'll never have enough energy to get through a day.

We now have a nice finished wood box for the remotes that sits right next to the TV. We use it even when the grandkids aren't here, just so we can find all five of them when we want them. It gets moved to a higher shelf when the young 'uns visit.

73's,

Bob McConnell

> Hi

I'd worry about several things. Most of the guy stress will attempt
to pull upwards on the anchors vs. trying to pull the anchors sideways
through the soil... You'll need a deeper and wider guy anchor base.
Most tower manufacturers show the guys out quite a distance from
the tower to minimize the upward pulling.

I'd also worry that a lot of the wind loading will try and twist the
mast and crossbraces so that the whole structure might tend
to corkscrew and collapse.

I'm not a structural engineer either, but I'd seek the advice of one
before trying something like this.

I just purchased a couple of the PK-Basic keyer kits from Jackson Harbor. Very small; I plan to mount one in a mini-Altoids box -- smaller than the common Altoids box. Here are a few questions for anyone out there who has experience with this keyer:

1. Keyer needs 3 to 5 volts. How about running it off two or three watch batteries?
2. Keyer needs a piezo transducer (basically a very high impedance speaker) so you can hear the sidetone. Can't I just use an RC circuit and use common ear bud earphones -- the kind you can pick up at Radio Shack or any other place that fine electronic equipment is sold?

Thanks.

Don't screw with Mother Nature. Guy wires are run out from the tower to
distant points for a reason: Because that's what works and all else fails.
Believe it or not, the folks who manufacture and sell towers know what they
are talking about.

It would work *if* the guy wire, support brace, and mast can handle the stresses, the mast can handle the twist put on it by the guy wires & braces & any antennas during high winds and the base is large enough to support the free-standing assembly. It would be similar to a free-standing tower.

In the typical guyed tower installation, the guy wires translate side pressure on the tower into downward pressure as well as preventing the tower from twisting. The base of a guyed tower can be rather small because it primarily needs to support the downward pressure. The base of a free-standing tower needs to be much larger because it needs to keep the tower from toppling over and from twisting.

Some stores ignore safety issues yea round. You go into some places that use the high shelving like in a supermarket, but eight to ten feet tall. One side is loaded with lightweight items, and the other has heavy appliances and the top is six inches out of line. They are exceeding the design strength of the shelves, and one day, they will tip over, or a couple welds will shear off, and the thing will fall. Probably when someone is trying to lift a heavy box off a shelf, and it will all come down on them. Some places refuse to listen, and the local morons don't see the danger, so i do not shop in those stores. I guess someone will have to die before they pay attention to the danger.

As far as too many lights, the electric bill is too high because of electric heat, so I don't bother with a tree or lights. There is no one in the house under 50 so Christmas is in the heart, not the house. I might put a string of ten miniature bulbs up around the glass in the front door, but not if I have to dig very far to find them. I have trouble enough walking, and even standing some days to worry about something so frivolous.

I am rebuilding a Heathkit SG-8 signal generator as described in November Popular Communications. the article says to replace the selenium rectifier with a 1N4007 silicon diode and a 100 ohm resistor in series. Does it make any difference what order the diode and resistor are in. would I install the resistor between the power transformer and the diode or does the diode come first. Also I used 450 volt 22uf filter caps instead of 160 volt 22uf that were called for. I think capacitors can be replaced with higher voltage caps am I correct. 73 Ed

You might gain a bit of surge protection for the diode with the 100 ohm resistor on the xfmr side but this is normally not an issue with an xfmr operated set. Voltage wise it won't make any difference.
The 450 volt caps will be fine. The only caveat here is that since they are working way undervoltage they may 'form' to that voltage and never be good at their full 450v rating in the future. Not really an issue unless you plan pulling them out to use elsewhere.
Actually, thats a piece of "TV Shop Lore" that was true with older caps but I really don't know if its the case with modern units. I have heard that it was no longer valid but others insist its still true.

-Bill

4150. Third party CTCSS Sources

From: jordan@accesscable.net
Message-ID: <2a4ddbec.0211300719.6d117836@posting.google.com>
Source record: 39567

Hello, I'm trying to get a MAX712 based charger working for a 14 cell AA pack. I'm trying to follow the datasheets "Typical Operating Circuit" design and I'm running into trouble with the high DC IN voltage that I will have to use.

In fig 5,pg 9 & fig 15,pg 15 of the datasheet it shows how to deal with high DC IN but in the evaluation kit it has not used these at all. Since the evaluation kit says it's possible to charge up to 16 series cells it leaves me with a few questions:

1) Do I need to use both of these voltage limiting circuits or can I just use one? If so which one?

2) If I do use both what happens to the 500 ohm resistor attached to the gate of Q1 and the DRV pin,(fig 15) when the 2N3904 is placed at the DRV pin,(fig 5)? Do I get rid of the resistor or do I attach it to the drain of the 2N3904 and the gate of Q1?

Thanks for your help
Jordan

Here are the two datasheets for the circuits:

You can substitute 450 volt caps without problem.

The order of the resistor and diode are not critical. Just
make sure the diode is orientated with the Cathode band
towards the positive end of the first electrolytic. As Bill M.
noted, you can probably delete the resistor; it's not a big
issue in that circuit.

If you have anymore queries regarding the SG-8, you can
contact me direct at RadioConnection@juno.com

Generally, adding a third party CTCSS board is not difficult. They usually have enough drive so you can use a fairly high value resistor and connect it to the microphone input.

There are a couple of problems....

One problem is, it is not easy to change the PL frequency when you install the CTCSS board inside the radio. You may want to mount it in an external box with a couple of connectors so you can connect the microphone to the box and then a second cable from the box to the 2 meter rig. This way, you have the CTCSS board where you can get to it to chenge the PL frequency. Maybe even set up a selector switch of some sort for the PL frequencies you want.

The other possible problem is a possibility that the very low frequency PL tone might disturb the radio. A unit I modified once injected the audio into the phase lock loop and that was how they FM'd the signal. Trouble was, the PL tone was in the phase lock loop bandwidth. Well..... That's a problem.

Anyway, a CTCSS board is fairly cheap, and it will most likely work for you but be prepared for the possibility. It depends on how the radio was designed.

Absolutely no problem, since the radio is designed for a PL board.

Do not feed the PL into the mic input, most FM rigs tailor the audio
response, the PL should be feed as close to the modulator as possible.
You'll need to determine which pin for the TU3 is the PL tone input.

The biggest problem you will have is setting the PL deviation to
600 or 700 Hz. If you don't have access to a service monitor, the
easiest way is to use a setting just above the minimum setting that
will reliably key the repeater.

>calculate how much?

Heh, heh, caught me there! The formula for an equivalent RMS
value of voltage from a resistor is e = SQRT(4*k*T*B*R) where
k=1.38*10^(-23) [Boltzman Constant], T=temperature in degrees
Kelvin (conventional standard is 290 K but I like to use 300 to
310 K for reality warmth in enclosures), B=bandwidth in Hz,
R=resistance in Ohms.

At 300 Kelvin and 3 KHz bandwidth, a 562K resistor would
generate 5.28 uV. "Noisy" if used in a direct-conversion
receiver! :-) :-(Fortunately, there is voltage preamplification
ahead of the network. On the other hand, random noise adds
in power so that the total from four network arms results in
total noise about twice that of the single resistor (very rought
approximation). Random noise won't be "cancelled" by any
audio differencing by op-amps following the network.

>networks vs the I-Q active opamp phase shifting.

We have a slight disagreement there. If there are four switched phases resulting from the multiplexer-switch control lines input from the dual FF, then there will be four phases of switched RF out of the multiplexer-switch...which reduce, in a rather horrendous equation to the "baseband" (audio, the CW beat or sidebands of an AM signal) and "pulsed" RF from the antenna on through the switch. The 47 Ohm resistor in series with MUX input and the capacitors in shunt with each MUX output form an R-C lowpass so that the "baseband" or audio predominates into the polyphase network input.

With only on-off keyed CW or pure SSB no-carrier there isn't a real need for any polyphase network for just hearing beeps or the pure SSB voice. Any convenient audio filtering can be done. But, with the polyphase network and summing-differencing of audio from the output, one can create a sort of "stereo" effect based on the spectral content on either side of the local oscillator. The left ear could listen only to the low-frequency side of the LO while the right ear could listen only to the high-frequency side. Several examples of such "stereo" audio from HF receivers have been done with articles in the Antennex site to at least one in QST. I kludged up such a detector in the late 1970s for a Heathkit receiver. It has a very interesting effect of letting binaural hearing "filter" QRM to one "side" (ear). When tuning with high gain, the effect is most unusual of background noise seeming to move right to left. Has to be heard to be appreciated... :-)

>Another factor affecting balance is the capacitors in the detector
>themselves. It is often overlooked but I believe these should also be as

>opposite sideband is still very invisible.

To get nit-picky, the On resistance of the MUX has to be determined as well as the tolerances of the capacitors (on-resistance in series

with the single 47 Ohm resistor at MUX input). At 300 Hz there
won't be any pronounced unbalance from 5 or even 10% tolerance
caps. Might be more at 3 KHz. Should be an easy thing to
calculate...but note that it also affects relative phase as well as
amplitude. Off-hand I don't think it is of great concern.

>> I did a response analysis of your polyphase circuit using 10 Ohm

>
>That's very interesting. What analysis program are you using? Is it
>something I can download from somewhere and try out?

Some SPICE programs will handle this network...free demo
versions can't do it because of restricted node and branch
limits (roughly 140 branches and 36 nodes). I use my own
shareware program LINEA which was released in 1993. DOS
level only, frequency-domain analysis only, it isn't attractive
to the eye but very accurate (double-precision every calculation)
and proven. I'll attach a 306K package in private e-mail to you..

>That's very interesting. The 4-path polyphase network is also (I have read)

>lossy, leading to more amplification requirement and thereby noise - until,
>that is, Yoshida's version which is loss free over the audio band. In my
>opinion this is an excellent receiver configuration.

I get a slight voltage gain of the Yoshida version of the Gingell
polyphase, about 1.6 X at mid-band. The analysis model assumes
a low source impedance (10 Ohms) and 22 MegOhms termination
resistors (rough estimate of some FET op-amps I've used). On a
quick check there didn't seem to much effect (less than 0.1 degree
and 0.2 db) of changing either source impedance (to 50 Ohms) or
dropping termination resistors to 10 MegOhms.

In the Technical Topics column of Radio Communication of 1973,
the "standard" Gingell network had only 0 and 180 degree input
phases but the output phase response over 300 Hz to 3 KHz was
quite adequate for conventional 40 db rejection SSB demodulation.
The Yoshida version with the four-phase Tayloe Mixer input is
MUCH better in response and together could make a "high fidelity"
AM receiver if so desired.

Keep on slinging that solder and keeping the website up to date!

Hi Michael,
As mentioned before I have been toying with a similar idea.
Tonight I pulled out my old Galaxy V 5.0-5.5 Mc VFO and decided to do
some tweaking to see just how low it might go.
By adjusting the coil slug only I was able to move down about 275 kc.
So I started adding more capacitance across the tuning cap. At around
270pf I got it down to 3500, with a tuning range of almost exactly 3500
to 3600.
If you know the Galaxy VFO, it has a very silky tuning and the dial tics
are in linear 5 kc steps. I think with a bit of tweaking I can get them
to be exactly 1kc tics and relatively linear across the dial. Boy, the
feel of the tuning is great in this range.
Moving this particular VFO up to 7 Mcs would result in touchier tuning
than the original 5kc tics but I wouldn't suspect it would be so touchy
as to be prohibitive. If I can unstick the coil slug :-(I might give
it a try just to see.
There is also a bandpass xfmr in the circuit. It still peaks well at
this frequency range without modification. Actually the VFO has more
output than at the original frequency, 5.5v p-p vs. 3.5v p-p according

to my crude measurements.
My intended use is with a Harvey Wells Bandmaster which prefers a 3.5 fundamental right thru 15 meters and of course my main interest is the CW frequencies. I suppose if I wanted to try 80 AM I could switch in a different cap or something.
So, the idea of modifying yours might have similar merit. This mod should work out great in my situation.

Many of the old LF masts from the early days were guyed like this,
which is why tall jib-headed sailboat rigs were called Marconi rigs.
Take a look at how sailboat masts are rigged to get some ideas.

If you took the next step, and put guys from the spreader points to
the ground, you'd have a steady mast, with the guys in a smaller area,
but you have to take into account the compression load on the mast, and
the upward loads on the guying points. Most materials are strong in
compression, and bend more easily, especially tubing, so you can trade
the one for the other. I use some of this myself, to counteract
horizontal loads using a lightweight mast, such as using light tubing
as an end support for a horizontal wire, very nearly on the lot line of
my property.

DO NOT attempt to insert the tone at the mic audio input. If the radio is properly engineered, there will be a high pass filter in the mic circuit that will roll off freq's below 300 Hz. You might be able to get enough tone thru the mic input to bring up the repeater, but you will have a number of problems if you go this route. Comm Spec has application notes on their site for most of the popular radios. Download the one you need and follow their instructions. Good luck, and 73

Hi Larry,

>The 4th Edition VHF manual (by Jessop), pages 5.23 and 5.24, has a reference
>schematic and basic ckt description of what you seek. Add'l reference in the
>Jessop book is "Electronic Engineering, June 1978"
I forgot to mention in my first post that it was in fact Jessop's
mention of drain mod that got me a searching only to come up with zilch.

Maybe the quality wasn't 'all there'.

However, thanks for the feedback.

I'd suspect the oscillator is breaking into parasitic oscillations, short
of
having a spectrum analyzer, a good wideband scope should give some
indication of what is going on. The difference between multiple caps
and a single component is the overall change in lead inductances, it's
not necessarily bad to use to multiple caps in parallel to reach the
needed capacitance. You might find a single NPO ceramic disc
exhibits the same problems in that circuit. One trick you could try is
a 68 to 120 ohm resistor in series with the control grid or plate, that
should help with the parasitics if they are the cause of the problem.

Also, a disc cap with a slight negative co-efficient might lead to better
frequency stability with warmup. Something else you need to play with.

Pete

Yes, it definitely shows on the scope. That confirms what I hear on the
receiver :-)

The difference between multiple caps
> and a single component is the overall change in lead inductances, it's

Thats not the problem in this case. My 'working' combo is a 270 pf disc
in parallel with a 22pf SM. 270pf or 300pf SM give the nutty operation
as do any combo of SMs.

> One trick you could try is
> a 68 to 120 ohm resistor in series with the control grid or plate, that

Ok, I'll try that and see if I can also find a ferrite bead later this
evening.

BTW, here's the schematic....

Actually, Kevin is right. I had a schematic for the rig I was fooling with and I knew that it did NOT have much audio shaping but most radios do and that has to be allowed for when hooking up a CTCSS board.

I tend to turn my brain off on weekends... Ah well, at least there are people here to catch my errors.

Absolutely correct advice. Two problems in particular become evident
feeding CTCSS in thru the mic processing chain:
(a) dev limiting will strip the CTCSS off completely, so you will
experience serious "talk-off" problems originating in your Tx.
(If you don't believe me, try it and watch it on a comms monitor).
(b) the dev you get (below limiting) will be a function of frequency,
as a result of the rolloff slope of the high-pass or band-pass filter
in the mic amp.

MOST transceivers have a proper CTCSS insertion point, which is
generally evident from examining the cct diagram. Note also that
tone-sequential calling tones ("Selcall") should be inserted through a
different point to CTCSS, and if there isn't a dedicated point for
this you will need to feed these down the mic chain.

I am working on a project for a class I am currently enrolled in and need to construct a zero-crossing detector FM demodulation circuit.

I know the specifications of the incoming FM'd signal:
fc = 122kHz.
fm = 5kHz.
deviation/modulation of 5.

I was wondering if anyone had any circuit diagrams that contained such a device and the constraints for tuning it to recieve the aforementioned signal.

Thanks.

Mike Koss

Ok, here's my fix. There was no easy way to fit in a resistor or bead
because the grid pin of the tube socket is the tie point for a wad of
components and its vey inaccessible. It was a series-tuned Colpitts
(Clapp?) circuit and I switched it around to be parallel tuned. Voila.
Clean as a whistle. A little less tuning range - about 65 kc which is
fine for me. However that shoots the nice dial calibration idea I had.
With the parallel scheme I can't stretch 100 kc out of it however I'm
thinking of going back in and see if I can squeeze it down to 50kc.
That would make the existing dial markings line up.
Next problem...I calibrated the scope and darnit the main output I was
getting was showing up at 5250 and not 3500. Further checking reveals
1750 was there also. I wonder if the original 5 MHz circuit was
actually running at 2.5 and doubling? No GDO to check with.
Anyway, not to worry. I put 220 pf across each side of the bandpass
xfmr and it now picks out the 3.5 signal quite cleanly.
Final test will be to see if the 2.5 v RF that I have left will be
enough to drive the old Harvey Wells.
Drift? Solid as a rock.

-BM

Hi Mike,

The easiest way to demodulate an FM signal based on the zero crossings is to feed it into a monostable circuit input. I assume the 122KHz signal is a rectangular pulse. If not, it is relatively easy to make it.

The period of the monostable should be slightly lower than the minimum signal period. I assume that the monostable is triggered by say the rising edge only.

Let's see what the monostable period would be...
Firstly, the max frequency would be 122+5*5=172KHz
The period of the 172KHz signal is 1/172KHz=5.81us
I guess a 5us monostable would do the trick. Take a look at the 74121 monostable.

Now, in order to get the demodulated signal, just filter the monostable output with a simple low pass filter which cutoff frequency is significantly lower than 122-5*5=97KHz, but higher than the highest freq in your modulation spectrum. The filter could be a simple RC or something more elaborated, depending on what you want.

The main disadvantage of the zero crossing FM detector is that the gain and S/N ratio are very low. But they are realy easy to implement.

Sorry no schematic, but if you find the above difficult to follow, I can give you more details. I need more details too :-)

Good luck,
Cirip

The advantages, on the other hand, are low cost, easy adjustment, and excellent linearity. I first encountered this method around 1970, in an SCA receiver used for receiving Musak-type broadcasts. Since it was intended for use in urban areas, sensitivity wasn't an issue, but low cost and linearity were. I adapted the receiver for use in demodulating slow scan video using a technique that required response down to DC. The video was being sent on a subcarrier to provide pictures to go with lectures being transmitted on a college FM station to its extension campuses. Worked fine.

>The main disadvantage of the zero crossing FM detector is that the gain and
>S/N ratio are very low. But they are realy easy to implement.

Gain doesn't matter, in itself, but why is the S/N low? That DOES
matter, and makes the low gain important.

4188. Racal RA1772 xtal filters (1.4MHz)

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-12-02 10:53:58 UTC
From: la8ak.xnd@online.no
Message-ID: <3deab7b0.99231188@news.online.no>
Source record: 39601

Based on info from the handbook this list is written

my RA1772 receiver has the following 1.4MHz xtal filters:

BD45249 3kHz symmetrical
BD45249 (5) (3kHz BW LSB)
BD45250 (2) (1kHz BW) symmetrical
BD45251 (6) (300Hz BW) Carrier, symmetrical
BD45253 ISB Carrier (300hZ BW?)
BD45274 3kHz USB/ISB (alt. for BD45858)
BD45275 3kHz LSB/ISB (alt. for BD45859)
BD45694 6kHz LSB
BD45695 6kHz USB
BD45806 13kHz BW symmetrical AM
BD45858 3kHz USB
BD45859 3kHz LSB
BD46975 (3) (600Hz BW)
BD46976 (4) (300Hz BW)
BD602856 (1) (2.7kHz BW USB)

(*) indicates position on IF filter board in my receiver

The filters seems to have 1k5 impedance with 68pF on input and 33pF on
the output (probably stray capacitance add to this)

It seems that other receivers uses 1.4MHz xtal filters, do you know
which filters have been used for other receiver which might work for
RA-1771 and RA-1772 ?

Hi,
hr is (1) Set of Sinclair P-201g 4 cavity Duplexer w/ Cabinet That I am selling. 24" tall cans X 6 3/4" Dia. with all the Cabes ready to go...just tune to your Freq. Pics of F-201G Sinclair Duplexers.....All Aphenol Connectors & Good RG214 Cable.

P-201 GR

The P-201G bandpass duplexer combines Sinclair's high Q bandpass cavities into a unit of superior performance in the 132-174 MHz range.
These Duplexers are easily field-tunable and feature rotatable lops for selectivity settings other than the performance detailed below for 0.5 dB per-cavity loss. In addition, vernier tuning is provided for fine frequency adjustments. Because of carefully designed temperature compensation, frequency drift over the operating temperature ranges extremely small, typically 0.5 ppm/�C.
These duplexers are available in rack-mounted or cabinet configurations.

For Specifications go to this site.

<http://www.wiscointl.com/sinclair/BaseStation/p201gr.htm>

$550 w\Cabinet
$500 wo\ Cabinet

Will Meet with buyer 1/2 way from Baskin, La.71219
upto 150 miles.

Hi Dave,
silver mica caps are really hard to get. I found some from old
supplies at http://www.mybox.cz/compo/slidy.html .They are rated for
500 volts, but if you connected e.g. 3 pcs 33 pF in series, you should
get where you need. They are axial types in plastic (epoxy ?) coating.
The contact to the supplier is compo@atlas.cz

Look up 'cathode modulation'. Not exaclty what you are looking for, but it should give you some basic principles.

This method was used with low power tube (valve) transmitters. A typical technique that I have seen was to use a carbon microphone as part or all of the cathode resistance in the amplifier. It was possible to build an AM transmitter with only two (or one?) tube (no audio amplifier). One problem, however, was that you could not get very deep modulation, usually no more than 50 to 60% if I recall.

Drain, collector, anode, amplitude modulation are all dead simple.

Just drive the carrier input (gate, base, grid) very hard to ensure saturation and audio modulate the DC supply volts between zero and twice the mean DC supply volts.

Most simple modulating devices are source-follower, emitter follower, cathode follower.

Brute-force and ignorance but it works every time! What's the problem? Havn't you done it yet? You have passed the RAE havn't you?

It's the Devil wot makes me do it.

I had a copy of a book called "engineer's trade secrets of radio", many years ago. I think it was by R.T. Cunningham, but am not sure. It was about 200 pages, and had many schematics for constructing tube-based a.m. transmitters. I have moved twice and cannot find it anywhere. It was blue and white about 5 by 6 inches, with some poor photographs of coils and transmitters, but had some good information.

I have searched the net and amazon with no results. can anyone help me? I have most of a transmitter built to his specs, but never finished it. I need the book to help me out! The author was a radio engineer, and sold plans and complete transmitters.

e-mail me if you can help, or have a copy I could purchase.

It isn't quite so easy to get clean modulation by varying the
collector supply. You wind up with combined AM and PM and a distorted
modulation envelope. This is particularly a problem as you get towards
100% modulation and with modulating frequencies > 1 KHz.

If you only are concerned with 30% modulation depth, then I agree it
isn't difficult.

4206. FT101 6JS6C to 6146 conversion advice please

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-12-03 07:45:52 UTC
From: Dave Bullock <DaveB@ihr.mrc.ac.uk>
Message-ID: <3DEC6130.2030300@ihr.mrc.ac.uk>
Source record: 39619

I have recently aquired an FT101 less output finals, and I am
considering converting it to 6146's.
I have the ZS1J (QST) article on how to do this but am a little
concerned about the voltages vs valve ratings.
Also which suffix of the 6146 to go for.(straight 6146, or A,B or W).

I have 6146W's readily available in matched pairs so was considering these.
FT101 seems to have around 700Vdc plate voltage and 160V screen supply.
(I haven't meaured what it 'droops' to, on load)
Also the ZS1J article recommends that the screen connection be removed
from the 160v point and be connected to the 300V driver stage supply.

The data (for all 6146 suffixes, A,B&W) states that for ICAS use, the
maxumum plate voltage is 750V at a screen voltage of 160V! So why does
ZS1J connect it to 300v? The datasheets also state that the screen
should be fed through a resistor of between 40-56K ohms, the FT101 seems
to only have 100 Ohms!

Has anyone carried out this modification successfully, or have any
technical insight that would be useful? I would appreciate your comments.

Thanks in anticipation.....Dave

In Phillips Application note AN170 there is a VCO design (fig 25)
that I would like to view, but all the PDF reproductions I can find on
the web are so low on resolution that the diagram is unreadable.

So, has anyone got a 'paper' version of Phillips AN170 that they could
scan Fig 25 for me ?.

Otherwise, I'm looking for an audio VCO with a fairly linear output
for an input of 0-5v, preferably using the 555 or similar common
device.

any offers?.

many thanks Mike W, G8NXD

hi,

can you still get those function generator chips? (max038 or similar
name??). would be better as a VCO than a 555.

555's and 741's are for college projects imo :)

Try the VCO in a 74HC4046 PLL chip. Simpler circuit than the 555 and much
less power.

The 'W' is a stronger envelope only - the 'B' has more dissipation.
I used 300 on the screens at abt. 900v on the plate.
The Radio Inspector put it on his analyser and pronouced it
'fine'. It was emitting 180W PEP.

It had the 'B' tubes.

Cheers.
Murray

There was once in Electronics Australia an article abt.
using a 555 as an audio amplifier. I wish I could point
you the right way to find it but can't.

They said at the time it was a 'fun' thing to use the
'ol 55 for something new and different! :-)

Could it have been a supra audio oscillator with the audio
fed into the control voltage port?

I do remember they said the speaker would reject the
hi freq and pass onlt the audio.

Dunno.

Cheers.

The output of the 555 VCO wouldn't be a sine wave, so it does not appear
to be too useful for audio....
MAX038 has already been suggested, XR2206 or ICL8038 are two other
alternatives.

I passed the exam in 78. Dropped out of component level work soon after.

Since then I've become brain dead.

It's all a new experience for me as I'm re-kindling my interest in
finding out what makes things tick.

It's nearly 25 years since I applied volts to the top of an 807:-)

> BD602856 (1) (2.7kHz BW USB)
>

Jan-Martin, This is not the standard list for this Radio. I note the apparent lack of an AM filter, usually 6,7 or 8 KHz wide.

Also BD 45249 is a 3 KHz symmetrical filter, not LSB.

The carrier filter (BD45253) for those radios fitted with the AFC option is 100 Hz wide, and can be linked to be used for CW, the wiring is fitted to the filter switch, you just need to move the switch stop.

45250 and 45251 are the ones usually fitted for CW use.

A lot of the radios on the UK surplus market and thus ebay have been fitted with offset data filters for use with data on one sideband and voice on the other. You may have one of these. I don't recognise your number 3 and 4. The 4697* numbers are not in my book.

These filters are spec'ed for 1 K with 75 pF in parallel, so that is what you need to look for. A lot of the filters offered on ebay as being suitable for the 1772 and so on are 50 Ohm, so watch it! You can probably find the 2.7 matching LSB filter on ebay as well.

Remember the radio inverts, the actual USB filter is for listening to LSB signals, and vice-versa.

I don't know much about RACAL receivers, but about twelve years ago I
obtained four crystal filters at a hamfest. They are marked:

"Alpha Components Inc.
Model 20509 P/N CO6986
C.F. 1.4 MHz BW-500 Hz"

I built an 80/40/20 CW transceiver around two of these filters,
keeping the other two as spares. The guy selling them had a whole box
full but I didn't know anything about them so I only bought four.
(Yeah, I KNOW!!!). Input-output Z appears to be 1000 ohms resistive.
You don't want to know what I paid for them.

There's one just like my four on eBay at present, if anyone wants to
see a picture. I don't know the seller.

Anyone have more info?

>i'd like to remotely measure inductance/capacitance
>in an remotely controlled 'L' network i am contructing.

Hi Larry, Making some assumptions-you would like to know when your "L" network has transformed the input impedance of the antenna to 50 ohms to match the coax going back to the shack. A 50 ohm swr bridge, bi-directional wattmeter, or an antenna analyzer will tell you that back in the comfort of your shack.
Not sure why you need to know the inductance and capacitance values in the L net. If you have the capability of remote L and C readings, you would also need to know the antenna impedance at the frequency of interest. Then you could use a Smith Chart or other such tool to get the L and C values for a match, but this seems like a lot of trouble.

Good luck finding the MAX038 -- they are backordered until the second coming.

The Nat Semi LM2907 is a good voltage to frequency converter (can also be used as a F to V), and the linearity is very good.

You can measure the impedance at the end of the coax by using a slotted line in the shack. You put a short at the far end of the coax and find the maximum and minimum voltage on the slotted line. The connect the load and do that again.

From those measurements you can calculate the Inductance / capacitance of the load.

There are other ways easier but they take more hardware.

Source record: 39639

What tools would you recommend for someone who wants to start out in the homebrew hobby and who simply accepts surface mount devices as a fact of life? Let's say I have a budget of about $500. I assume at a minimum I need some type of hot air rework station and some software that will let me lay out printed circuit boards with surface mounted components. Is anything available in that price range, and what other items should I be looking for to equip a workbench?
I have decided that I would like to take up the homebrewing hobby. After having found a scematic and trying to scrounge up the parts needed for even a simple receiver, I have decided that the logical thing to do is learn to deal with surface mounted components. Most of the IC's I wanted are available in SOIC package but finding DIP packages was a challenge. After trying to find certain ICs it seems money would be better invested in some type of rework station than a drill press.

SMD do not really scare me, I have been able to solder SOIC onto an adapter board using a very fine tip and a temp. controlled soldering iron. But that was difficult and I cannot imagine working with anything smaller than SOIC with a soldering iron. I realize that any job is made much easier with the proper tools.

I have seen some rework station go on ebay for around $200-$300 but I really don't know what kind of features I should be looking for, or if there are new otions available at reasonable prices.

Well, a vacuum parts holder/placer is handy, along with a good illuminated magnifier lamp. My Soldering station is an old Pace unit I purchased on E-Bay for $200. I spent another hundred on all the various tips specially designed for SM devices. My soldering station not only sucks, but it blows. This is a good thing :-) A small stream of heated air flows solder nicely around contacts.

The vacuum parts holder/placer I built myself. It has two handwheels for XY axis movement of the part and a foot switch for Z axis clamping onto the board. It makes setting the part onto the board much easier and eliminates movement of the part when soldering with direct heat or hot air. At first I used the vacuum pump in the Pace but later added another stand alone pump with a two position foot swich. One click forward for vacuum on, two clicks forward to clamp the part onto the board.

See other threads in this group for the PCB software. I use PADS but there are lots of fairly good free packages on the net.

> device.

Hi Mike,
I have a measurement protocol of a 555 VCO sample at hand. It is a
common astable multivibrator:
Vcc = 9 V
pins 4 and 8 to Vcc
pin 1 to GND
D.C. modulation Vmod to pin 5 (decoupled by a 6800 pF capacitor to
GND)
output from pin 3
1000 ohm resistor between Vcc and pin 7
560 ohm resistor between pin 7 and pins 2,6 (connected together)
0,15 uF capacitor between pins 2,6 and GND

The VCO works only when 2,7 V <= Vmod <= 9 V

Vmod [V] f out [kHz]
2,7 15,6
3,0 12,7
4,0 7,2
5,0 5,8
6,0 4,6
7,0 3,4
8,0 2,6
9,0 1,6

I hope this will help you.

If you are only going to assemble the occasional PCB, like most of us, you don't really need anything other than a good soldering station, tweezers, magnifier and some narrow desolder braid. Don't go smaller than 0805 for Rs and Cs, and you shouldn't have too many problems.

>
> SMD do not really scare me, I have been able to solder SOIC onto an

> proper tools.

The best technique for fine pitch devices is to flux the pads, tack down two leads at opposite corners ensuring all the leads are aligned correctly, then 'flood' the leads and pads with solder, using a largish tip. Remove all the excess with desolder braid, remake any suspect joints (finest tip), and that's it. Metcal, who make the best soldering equipment, recommend this method for hand assembly, and even sell a bit specially made for the purpose.

If you are designing your own PCBs, it's a good idea to make the pads longer. The standard footprints are intended for solder paste, not hand soldering.

A gas iron like the Weller Pyropen with a hot air nozzle is useful for removing chips.

>You can measure the impedance at the end of the coax by using a slotted
>line in the shack. You put a short at the far end of the coax and find the
>maximum and minimum voltage on the slotted line.

Or you could use Lecher Wires. Neither are practical at HF frequencies. I
used Lecher wires about 30 years ago to determine the frequency my 1 tube 6cw4
70cm transceiver was tuned. Worked great.
I thought with the abundance of antenna analyzers and impedance bridges
nowdays that slotted lines and Lecher wires were confined to college microwave
labs. They are a great way to visualize what's happening on a transmission
line.

I think TenTec used to sell the manuals for their kits seperately. If you
can either get one from them or from someone who has built the 220 kit, that
should give you an idea of how to put one together.

I built their 6m kit and am very happy with it.
thanks, John.

Be aware that the VCO in the 4046 isn't particularly good - although I would say, in the interests of simplicity/KISS design, try it first.
I once needed to regenerate TV line pulses at 15625 Hz (PAL frame rate x full line rate) & ended up using the phase comparator of the 4046 with an AD654 (Analog Devices) V to F converter. I had initially tried using both VCO & phase comparator of the AD4046. The difference in the stability (lack of line jitter) was immediately evident both on a scope & on the received picture (this was a satellite signal descrambler from the days when it was all analogue).
You can get up to 2 free samples of most Analog Devices parts via their website.
I actually work for them - but that is not the point.
Chris Muriel (G3ZDM)

Try a hamfest. The Burnaby swap meet is particularly good.
Hell, try EBay.

Seriously, people crop up here all the time wanting to
build relatively complicated gear, and few seem to have
any idea of what they're getting in to. You're certainly
not going to save any money.

Last time I checked, building transmitters wasn't
something a Basic licensee could do anyway.

Laura, you bring up an interesting point. I have often wondered about the cost of homebrewing vs. the cost of buying. I have agonized over starting several projects that I eventually undertook and now, looking back, I spent more than I should have. I mean, have you looked at what a roller inductor or a variable capacitor costs nowadays? Ridiculous!

My theory is that if we always made the decision to homebrew or not to homebrew just based on cost, that nobody would ever homebrew.

It almost always costs more to build a tech device yourself. Name a piece of electronics that doesn't. The only thing I can think of is an HF dipole, which will cost you upwards of $50 to buy but far less than that to build yourself... and a dipole is really the lowest-tech device in the typical shack.

What costs less, buying the latest CD of a Beethoven piano sonata, or spending twenty years of your life taking lessons, practicing, and performing it yourself? But how can you make a decision like this based solely on price?

Maybe this thinking, more than anything else, is what's killing homebrewing in amateur radio.

Regards,

Al W6LX

I agree on costs. However I still home brew some equipment. My approach
Is to not design and then get the parts, but get some parts and then see
what
I can make. This makes for some sub optimum designs, but if it works I am
happy.

Parts come from surplus equipment, ham swap meets etc.

Hi Mike again,
what about the LTC1799 circuit ? Its frequency is set by one resistor (10 kiloohm < R < 200 kiloohm) in the range 5 kHz < f < 20 MHz. No other external parts (except a decoupling capacitor) are used. I think the resistor could be replaced by a FET to obtain a VCO. Smaller frequencies can be obtained using an external divider.
Just an idea.

Hi Al,
you are right. The main aim of homebrewing is to learn how the stuff works and to enjoy some fun. The price should be almost unimportant. It is the same case as with all other hobbies. "Monetary and market approach" kills them like a poison.

Tnx info!
My receiver has been used a coast station, not sure if it was medium- or shortwave. But the BD45249 works fine for LSB (80/40m ssb).

I am considering some mods.
First I will place a alu-plate on the rear for connection to loadspeaker, mute, cwkey (i/p) and other for the connectors I've standardized to in my shack (i.e. RCA phono and conhex).
Then I am considering a fast MUTE - without relays (don't like relays - removed half hundred douzens relays from operation when I worked at Rogaland radio 25 years ago). It seems possible to feed 3V from voltage divider to pin 8 or 9 on the First IF board to bias the PIN-diode attenuator towards off-state and reduce sensitivity when tx is keyed.

will also add an 1N4148 on AGC switch to enable use of IF gain when AGC is in operation, as for all the other gears I have in the shack

The first IF (35.4) uses the BD44454 filter- Wonder what is the selectivity? The second mixer isn't particularly good, but is said to have 20dB balance without any tricks

Couldn't agree more. I grew up very impoverished, and quickly learned to be resourceful. If I ever got bored, I'd get my junkbox and dump everything out on the floor, then try to figure out what I could build with what was there.

I scrounged a lot of stuff from local radio and TV shops. To me, this was half the fun. As a Novice, I worked 27 states on a homemade two tube transmitter. What a blast. Some aspects of the craft may have changed, but it's still possible to have a lot of fun, learn a thing or two, and not go broke.

I can't figure out a better newsgroup than this to post this question, so please accept a slighty off topic post.

Here in Seattle, I have two atomic clocks and neither will receive WWVB with any regularity. Is there anyone in the area (preferably in the city with all the QRN) that can recommend a clock that is actually locking onto WWVB?The other problem is just plain lack of signal. Seattle falls outside the 100 uv/m contour during part of the day - as does a lot of the west coast.

Chuck

Most clocks seem to sync up best during a short window during the
night-time hours. One trick is re-orientating the clock, the antenna
may be directional.

Good points, all.

Building equipment for financial reasons alone is nonsense,
and has been so for decades. YaeComWood and their ilk
can crank out gear for far less than anybody could possibly
build it themselves.

I see two particularly good reasons to build something
nowadays: to build a piece of equipment that is not
commercially available (either too specialized, or
weird specs that don't interest the YaeComWood bean-
counters), or as a learning experience.

Both are excellent reasons to build something, and I've
done both myself. However, both motivations require a
certain amount of experience; even in 2002, you must
learn to walk before you can attempt to run.

I'm in Tulsa, OK and I can hear anything on60kcs but the clock synch up in
the middle of the just after i put the batteries in it..
I took it apart to see what it had for an antenna and it's a 4 inch ferrite
loop and a couple of ICs and thats's it...
the designer certainly knew what he was doing..
I bought mine about a year ago at Scams for about $20 and now they're down
to less than $10.00 or $25 for oine with an outdoor thermometer..
why didn't wait?

I'm south of Ocala Florida, and I have no problem picking up the
signal. The signal level meter is full scale all the time. You may be
getting interference from something like a TV or monitor.

Yes, this is probably it. The signal here in Los Angeles is also very weak and usually makes it after midnight, but the position of the clock is really critical.

You need to move around the clock on the desk to find a good spot. Move it, then leave it overnight without touching it. Next morning, see if it got a good signal.

Keep the clock away from metal.

Orient the clock so that the ferrite rod antenna inside is broadside to Ft. Collins, CO.

It will take you several nights, but eventually you will find a good spot. Good luck.

Al

I live in the east end of the San Fernando Valley in Los Angeles
and have not encountered any weakness in WWVB despite
the Verdugo Hills at our "back" (towards Boulder, CO).

My wife and I have taken our Oregon Scientific "atomic clock"
to our second home outside of Tacoma and haven't had any
problems with it...only some loss of signal when packed inside
the car while driving up and back.

These little $30 clocks aren't a Wonder Radio capable of
working through QRM or QRN. Of course they might be
"critical" as to positioning. I am surprised and delighted
that the Oregon Scientific units work as well as they do!

you may build a stage or part of a rig, or a simpler rig if you would
like to try a particular concept. I've just heard that two OPs builds
a receiver with 7360 as mixer

>I see two particularly good reasons to build something

I would choose one of those YaeComWood, but they normally don't serve
my interntions, so a lot of mods are required to achieve the
performance needed.
Usually it is no provision for using transverters with the 100W RF
stage disabled, signals split into two coax cables, with +12V to
signal to start the transverter in the TX-coax. Also often a good
improvement to add a plate or bracket with standard connectors for
interface towards other equipment in the shack

Well, homebrew is definitely NOT practical for a SOTA HF transceiver,
but surplus converson, antenna tuners and small power supplies is
still a good area to start. Or boatanchor restoration.

Nowdays there's too many candy bars at the ham stores that the hams
have become "CBified". Pay your money and play with your toy.

There is nothing like the thrill of making something work with a bit
of blood, sweat and tears. Even simple projects give me that thrill,
after 34 years in this hobby.

As far as costs, learning how to be a good hunter/scrounger at hamfests is paramount. Being a typicl frugal ham I don't like paying retail for anything. With experience, one learns how to substitute parts, rather than relying on EXACT items.

Hummm. I was always curious what the exact difference between a "W" and a "B" was. I thought the W was a military version with the same appx specs as a "B". I was under the impression that they both had the same 35 watt plate dissipation. I know the "B" was 35 watts, with the old "A" 6146 having 25 watts dissipation. If the "W" is lower, what is the dissipation? I do notice most "B"'s seem to cost more...The 6146 was probably the best power tube made for that size tube. Much harder to kill than most sweep tubes. Drake 6JB6's in particular don't hold up to abuse with their puny 17 watt dissipation. I used to eat a set a year, back when I ran drake twins non stop. MK

"W"s are just ruggedized "A"s. The "B" is different enough that it interchangeability is an issue. Some rigs can use Bs and some can't. Others require adjustments like reneutralization or even minor circuit modifications.,

I think the main reason Drake and others used sweep tubes was that, in their time, they were less expensive and more easily available than 6146s! How times change...

The W supposedly had a more rugged filament. The 6146W can be a
regular 6146 type or it
can be a 6146B type depending on when it was made. Supposedly the
later W versions were
the same as the 6146B as far as electrical specs. The B came out some
time in 1964 but the W
did not adopt it immediately but some time after that. So if you have
W's after 66 or 67?? they
may be the same as the B.

As far as running high values of resistance in the screens, that will
raise IM. Also higher that
specked screen voltage will raise IM products. They should be run at
manufacturers spec on the
screens with a stiff supply.

> winding to prevent, shall we say, unfortunate accidents.

How would you add a LV secondary without removing the HV winding anyway?
It isn't hard at all BTW. I used a small cold chisel, sharpened a
little,and cut right through the winding in four places - straight down
the face of the core - then use a square punch (piece of wood) to push
out the remnants. Took less than a minute, and left the insulation intact.

Getting a hefty secondary winding in there was more of a nuisance.
Anyone care to share a smart solution?"
This is from a Newsgroup thread on reusing these transformers, if you
are going to run it for a long cycle time (not likely) you would want to
add a cooling fan for the transformer.

Hello,

I am designing an extremely low power (<<1 W input) AM transmitter and have encountered several difficulties including how to determine the impedance of the modulation transformer.

Suggestions on this or anything else (operating points etc) would be appreciated.

Thanks.

Joel

Thanks for the response. Being somewhat new to the homebrewing hobby, I am still a relative novice at soldering at all (unfortunately I never learned it in shop class). So I am now simply diving in having just owned a traditional temp. controlled iron about a year.

While it does get easier with practice, I freely admit that I am not the best solder-er in the world. I am wondering if working with a hot air station is generally easier, more difficult, or simply "different". So what kind of skills am I going to need to acquire if I want to start working with hot air rework stations? Or are those skills going to be totally dependent on what brand/type I purchase? I saw an infrared station go on ebay for just a shade over $500, and would like to see a comparison of that tool to the hot air stations for working with SMD.

Finally are there any good books and/or magazine articles you could refer me too that give advice as to getting started with hot air and/or infrared soldering.

4290. FS: Old Radio-Related Books (1930's-40's)

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-12-08 15:08:41 UTC
From: oldbooks78@aol.com
Message-ID: <20021208100841.04759.00000133@mb-fr.aol.com>
Source record: 39503

I currently have for sale the following old radio-related books. Postage is $2.50 for the first book, and $1 for each additional item. The books are:

Smith, Woodrow "Antenna Manual" Editors and Engineers Limited, 1948. The 306 page hardbound book is in very good condition, clean with no page tears or pen marks except for a previous owners name and address stamp inside the front cover. A few small white stains on the covers, otherwise tight and secure. The first edition of the Antenna Manual publication. A nice early radio reference book. Available for $10.

Federal Telephone and Radio Corporation "Reference Data for Radio Engineers, Second Edition" Federal Telephone and Radio Corporation, 1947. The 322 page hardbound book is in good+ condition. Clean with no page tears or pen marks except for a previous owners name and address inside the front cover. "The present edition has been greatly enlarged and a subject index included. Chapters on transformers and room acoutics have been added. The material on radio propagatiion and radio noise has been revised. The data on cathode-ray tubes have been considerably expanded." Available for $8.

Everitt, William Littell "Communication Engineering" McGraw-Hill, 1937. The 727 page hardbound book is in about very good condition. Clean with no page tears or pen marks except for a previous owners name and address inside the front cover, and a few passages underlined in pencil. A nice early text on the science of the radio. Available for $9.

Measurements Development Laboratory of the Sperry Gyroscope Company "Microwave Transmission Design Data" Sperry Gyroscope Company, 1944. Publication No. 23-80. The 215 page hardbound book is in very good condition, clean with no page tears or pen marks, and a strong binding. Originally issued during WWII as a "confidential" document. Chapter topics include General formulae for concentric lines; Attenuation in concentric lines; Reflections and impedance matching; General formulae for wave guides; Attenuation in wave guides; Reflections and impedance matching in wave guides; Wave guide tees and bends; Wave guides filled with dielectric material; Dielectric material: Cavity resonators; and Measurement techniques. A neat early book on ultra-high frequency radio waves. Available for $9.

Graham, Frank D. "Audels Radioman's Guide, Modern Radio Practice" Theo. Audel & Co., 1932. Tan cloth covers over flexible boards. The book is about 250 pages in length (pages are numbered oddly, making a total count difficult). A nice early vintage radio book, illustrated throughout. Clean with no page tears or pen marks except for a gift inscription inside the front cover. Cloth covers show some spotting and light staining from age, but not bad at all. Available for $10.

ARRL "The ARRL Antenna Book, 13th Edition" American Radio Relay League, 1977. The 336 page softbound book is in about very good condition. Clean with no page tears or pen marks. The covers show a bit of wear from previous use, but not bad at all.A comprehensive treatment of radio antennas. Available for $7.

Harrington, Thomas P. "Tune to Satellite Radio on Your Satellite System" Universal Electronics. First Edition. The 103 page magazine-sized softbound book is in fine condition, fresh and clean inside and out. Includes a separate "Chapter 8" dated September 1993 laid in. Available for $3.

Carrington, Eugene "Allied's Electronic Data Handbook" Allied Radio, 1959. Soft Cover. The 64 page softbound book is in very good condition, clean except for a previous owners name marked out inside the front cover. A compilation of formulas and data most commonly used in the field of radio and electronics. Available for $2.

Beam, Robert (editor) "A Dictionary of Electronic Terms" Allied Radio, 1959. The softbound 80 page book is in very good condition, clean except for a previous owners name marked out inside the front cover. Concise definitions of words used in radio, television and electronics. Available for $2.

Kiver, Milton S. "Understanding Transistors, Allied's Handbook of Transistor Fundamentals" Allied Radio, 1962. The 64 page softbound book is in fine condition, clean inside and out. Topics include transistor fundamentals, junction transistors, transistor symbols, basic amplifier circuits, radio- and intermediate-frequency amplifiers, transistor oscillators, and more. Available for $2.

Jordan, Edward C.; Paul H. Nelson; William Carl Osterbrook; Fred H. Pumphrey; Lynne C. Smeby; and W.L. Everitt (editor) "Fundamentals of Radio" Prentice-Hall, 1944. The 400 page hardbound book is in good+ condition, clean with no page tears or pen marks except for a previous owners name inside the front cover. Gray cloth covers with some minor spotting on the front cover, otherwise nice. A nice early radio related text. Available for $9.

US War Department "Technical Manual - Radio Fundamentals, TM 11-455" U.S. GPO, 1941. The 140 page softbound book is in fine condition, fresh and clean inside and out except for a previous owners name on the front cover. A nice WWII vintage radio manual. Available for $10.

If interested in any of the above, please email to "Oldbooks78@aol.com" to reserve. Thanks.

Dave

My eyes are not all that good and my hands are shaky, but give me a microscope and a decent temp controlled iron and I can usually solder and desolder many smd's. When you get down to pin pitches of 0.5 mm or so, then there's a real problem with conventional techniques. Hot air is fantastic, but expensive and still requires the magic ingredient; patience. Good, simple tips for soldering are: keep you tip clean (use a tip cleaner and sponge), solder to a clean interface by putting on flux if necessary, and don't force the tip down onto what you're soldering. Use a light touch.

4292. 2 meter yagi feedlines

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-12-08 20:04:40 UTC
From: John Koch <jakoch@centurytel.net>
Message-ID: <5e97vuk7qhvlma7fh1e9g72i9237uu1ufo@4ax.com>
Source record: 39505

I have just got into making antennas. I have made a couple for 2 meters. They work ok but my question is one I can not find on the internet. I am making some yagi beams and I am confused about the driven element. Some have the driven in two parts and therefor the feed line is one each of the elements... some have the driven in one peice centered on the boom. These antennas say nothing about where or how to connect the feed line. Can someone shed some light on this subject. I have been just cutting the driven in the middle on all my projects. Is this what I should be doing?

BTW, I am getting the ARRL book but thougt I would try to get this question answered first.

Thanks

I'll try :-)
First consider that the impedance of a typical properly tuned yagi is
something considerably less than 50 ohms. If you have been using a
split element I suspect that you are going out from center a couple
inches in either direction to attain a 50 ohm match.
A gamma match simply does a similar thing to one side only. The shield
of the coax goes directly to the center of the element and the center
wire goes a few inches out from center.
But it doesn't end there. This configuration produces a bit of
reactance and there is usually a capacitor in series with the center
wire. This may be a fixed value, a trimmer, or a trombone type of
assembly made with tubing.
Its a little more complicated but the solid element offers a direct
ground which may mean less precipitation static, lightning protection
and often easier/more solid construction.
No particular need for a balun is also an issue but that's a very
subjective subject anyway.

Hope this helps.

-Bill

An alternative to gamma feed or dipole feed is a Jpole feed, where the
driven element is a Jpole, it spans the middle ground between gamma and
dipole feeds.

If you do a search on "cheap yagi" you can find the plans for 2m and 440
versions of the cheap yagi. I built the 9 element 440 version and with it I
can hit a repeater with my handheld that I can't hit otherwise.
thanks, John.

4301. Tones on an FT-225RD

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-12-09 03:10:18 UTC
From: dss117@aol.com
Message-ID: <20021208221018.01467.00000187@mb-cr.aol.com>
Source record: 39514

I have a Yaesu FT-225RD 2 meter base. It does not have an internal tone unit to access the repeaters. I hope to add one. Has anyone done this with this rig? Where does the tone unit conect to the rig?
Any help would be great!

4302. Re: AM Transmitter

Source record: 39515

The method used by Ed Noll in his book "Radio Transmitter Priciples and Projects" is to measure the supply current used by the stage(s) to be modulated and divide that value into the supply voltage (remember, this is prior to any modulation being applied, just the carrier is present). The resulting value of resistance is what the secondary of the modulation transformer should be.

isn't antenna theory on the tests anymore?

you could also use a V-match to a ladder line. if you use a gamma match,
don;t forget to use a Pausey balun.

4304. Unknown pin assignment on oscilator

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-12-09 04:50:28 UTC
From: Marvin Kroll <merkinp@worldnet.att.net>
Message-ID: <oiVI9.50941$hK4.4411468@bgtnsc05-news.ops.worldnet.att.net>
Source record: 39517

I have several oscillators, each in a metal case about 2" square and 0.5" thick. The case has a label that includes a stylized logo that I can't read with certainty, but it may be NFC. There is an sma output(?) connector on the side and four pins on the bottom. One of these is directly connected to the case but the other three are isolated and are positioned at three corners of a square 1" on a side. Is this a standard pin-out? Where can I find the pin assignment? MK

As I recall, turns ratio of modulation transformer = SQR_RT(Z1 * Z2) where
Z1=Modulator impedance and Z2=RF power amplifier (or stage to be modulated)
impedance.

OK, here are 2 ways to get to the apps note :

1) Go to ADI homepage www.analog.com
Enter "AN-279" in search box & hit button

2) Enter AD650 in search box & hit button
Hit "Technical Library" link

2nd method gives a number of apps note related to the topic.

4316. Battery Charger question

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-12-09 18:22:45 UTC
From: Mark Symms <symmshsd@earthlink.net>
Message-ID: <Xns92DF7E15AE08Dmsymms@207.217.77.21>
Source record: 39529

Hi All,
I am currently trying to build a batttery charger for my Yaesu FT-416 HH. The battery charger hookup is an 1/8 inch headphone jack. My question is polarity. If the tip is negative on output does it have to be positive for charging? Also the batery is 800mAh, and the charger is 300mAh. How long for a full charge?

As you can tell I am no EE.
Thanks for any help
-mark

Source record: 39532

YOu hook the charger up to the battery so that the positive output of the charger will be to the positive of the battery. To findout how long it will take to charge the battery you devide the battery mAh by the charger current. If you have the 800 mAh battery it is 800/300 which is about 2.6 hours. To that you have to add 'fudge factor' which means that it will take about 3 hours to get a full charge. That is assuming the battery is designed to take a charging rate that high. Some are and some are not designed to take a charging rate that high. The battery can over heat and vent out some gas. Then it will not take a charge very well.

Not only do you need patience, the paste solder has a limited shelf
life, and is expensive to buy and dispose of unused, expired solder,
legally. If you are doing short production runs, the hot air station is
good. Some people only use them to remove parts, and resolder by hand.
I spent four years doing fine pitch board testing and did most of my own
rework. A good boom mounted stereo microscope, a Ungar Loner soldering

iron with a small tip and Ersin Multicore .015" solder performed very
well. Some of my rework is aboard the space station.

It's very frustrating to be directed to a dead page, but pages can
disappear without notice. It's best to check that the link works
immediately before you post, but that's not always convenient.

Any way you could take a picture of the label, or perhaps just scan
it? Is there a part number too? (Please don't post it here, but
perhaps to one of the alt.binaries groups or send by email to those
who ask.)

I suppose one pin is oscillator power, one is frequency control, and
one might be oven power if they are oven oscillators, or perhaps an
"at temperature" indication. Perhaps it's a pin that would be the
output if they weren't SMA output style, but isn't connected to
anything in this case. Of course I don't know for sure that they are
oven-controlled at this point, though we've used some that size that
are. I wouldn't count on any standard pin configurations...I've been
burned by too many that weren't when I thought they were! :-)

Cheers,
Tom

Can anyone point me towards an video amplifier module or IC suitable for a 2.4Ghz transmitter that has about 4mW OP? I just need a little more power; cheap and light is good ;-)

Thanks & 73's

Richard

You can get a 404 error if the URL isn't found on the DNS server used
by your ISP, or the files were moved to a new IP address, and the update
hasn't hit their DNS server. I ran into this a few years ago. One of
my suppliers changed their host, and i couldn't access them because my
ISP had their own DNS ideas, and it wasn't updated, but i could go to
another provider and had no problem reaching them. This went on for
almost three months, before they got mad enough to fix the problem.

Source record: 39543

Hello Folks,

I have a question to the ICOM IC-T81A in regards to the Battery operation.
This unit has only one connector to power it up via ac adaptor.
I am afraid to overcharge the battery if it is always hooked up to the
AC Adaptor.

A second thing that concerns me is is how to store the device - battery
harged or
empty ?

THanks for any help

Peter

I did some experiments with the AD831; it isn't too bad of a mixer. The noise figure is around 10dB, so by the time you put some RF amplification ahead of it, the IP3 is similar to a Level 7 diode ring mixer. One advantage is the lower required LO drive, but like the old 1496 mixers, quite a few external parts are required. I ran into the same thing when using the AD607 Quadrature I.F. strip, and shelved that idea.

Pete

4344. How much VFO shielding do I need?

Newsgroup: rec.radio.amateur.homebrew

Source record: 39407

My question concerns breadboarding HF oscillator circuits. VFO's (and other sorts of LC local oscillator circuits) are often built with elaborate separate shielding. What I'm wondering is whether it's possible to get a simple LC oscillator running well enough to evaluate its usefulness (for RF mixing purposes) in a breadboard fashion before building the heavily shielded version, or if the shielding should come at a fairly early stage.

If you prefer posts that "get to the point" please skip to the paragraph headed "Back to the original problem." If you like to know a little background, read on through.

My expertise level: Over the last 30+ years, Since the age of 10 or so, I've put together a handful of electronics projects, some from circuit diagrams and some from kits, including audio, digital, and basic radio projects. I've managed to make a few repairs over the years, too, but I must admit that diagnosis often eludes me. I do more reading than tinkering, but these days, I'm trying to shift a little toward doing.

My style: I'm a cheapskate. I'd much rather build circuits that can be put together on a whim by anyone with a pile of 2N2222's, and assortments of basic components like ceramic capacitors, diodes, and resistors, than the kind where I'd have to place an order for parts. A project I built myself with parts I'd stocked or scrounged, which I understood from start to finish because I'd tinkered with every stage of it, which worked somewhere between poorly and fairly well (depending on whether your rating scale is a little stiff, or like mine, rates as "fair" or better anything which works well enough to be used for casual QSO's) would be more valuable to me, personally, than, say, a project built from a kit that would hold its own against typical commercial offerings. What I learn is at least as important to me as the finished product. I hope to some day reach a point where I could build a reasonably well working ham station using nothing but parts scrounged from some old discarded piece of equipment such as a worn out computer monitor.

My current project: This is a meandering project. It started out as a plan to program a PIC chip for a huff 'n' puff VFO. (I'm a computer guy by profession, and I've done assembler programming before, including a little bit for microprocessors in control circuits, but haven't actually programmed a PIC.) The thing is, before I can program a PIC chip to control a VFO, I think I need to be able to build and control a VFO myself. So, I planned to play with some VFO circuits. Of course, it's important to keep this stuff fun, too, so I wanted to do something entertaining. What I came up with was to go ahead and do something I'd been wanting to do: make a "shortwave converter" for an old AM-only

car radio I bought at an estate sale for $3. Just to get the project going, I started with a crystal oscillator. (The plan is to replace the crystal oscillator with a LO, or VFO, or whatever you want to call it, when everything is working.) Next, I made a doubly balanced mixer, and a simple LC preselector. The crystal frequency is around 8.2 MHz, allowing me to receive the 41 and 31 meter SWBC bands using the AM receiver as a tunable IF in a band imaging scheme. Surprisingly, this thing works pretty darn well. Satisfyingly, it serves a dual purpose. It's an interesting project to tinker with when I get a chance, and in between, I get to enjoy a little SWBC listening.

Back to the original problem: The last time I got a few hours to work on the project, I tried to build an LC oscillator to use as an LO, rather than the crystal oscillator I started with. I used Harry Lythall's basic oscillator circuit:

http://w1.859.telia.com/~u85920178/blocks/osc-1.htm

...under "Tuneable RF Oscillator" a little more than halfway down the page. I wound a coil on a 1.25" pill bottle, and wired in a gear-driven 150 pF air variable (from an old ARC-5 or something, I think) for the tuned circuit, designed to include 8.2 MHz in its tuning range (factoring in the other three frequency-determining capacitors in the circuit, all NP0 ceramics). The rest was built in a corner of the Radio Shack solderless breadboard panel I've been building this project on.

When I tried to listen for stations when I used the new LC oscillator (followed by some further amplification) instead of the crystal oscillator I'd started with, the results were dismal. Tuning the air variable caused a horrendous cacophony of whines, groans, buzzes, and hums to assault the speaker. Experimentation convinced me that more of the raucous ruckus was related to my movements in the proximity of the tuning capacitor and my touching it, than to the actual adjustment of the capacitor. Moving my hand anywhere within a 10-inch or so radius of the coil and tuning capacitor varied the symphony of strange noises, as did touching ground anywhere on or around the project (which is currently spread all over the bench). Much to my surprise, the horrible sounds remained even after I disconnected the output of the LC oscillator, and put the crystal oscillator back as the LO. I had to cut power to the LC oscillator circuit before things returned to normal.

After I thought about it a bit, that last detail game me a major clue: If the horrible sounds weren't coming (only) through the mixer, how were they getting into my audio output? ...probably through B+. I'd totally neglected to include a bypass capacitor on the B+! Of course, Harry's "basic building block" circuit diagram omitted such details. I hope to have better results next time I get to play with this, when I'll insert a bypass capacitor and hook the LC oscillator back up. However, I wonder how much of the problem will remain. Those several-inch-long leads connecting the air variable and coil to the rest of the circuit can't be helping, either.

So, my question: Should I expect to have to build the LC oscillator in a shielded compartment of some sort before it will put out the sort of clean, usable signal the crystal oscillator is providing? I know that I could avoid some of the problem if I used a toroidal coil rather than the pill-bottle coil form I'm using, but, what can I say? ...I love to use ordinary everyday building blocks, such as pill bottles, whenever possible. Can one evaluate open-air solenoid coil LC oscillator circuits in a breadboard fashion? If so, what's the key to cleaning it up? Or, will I need to build a proper shielded enclosure to make it sing, even for breadboarding purposes? Or, to look at it another way: Are my current problems likely due to construction techniques, which I should correct before reaching conclusions, or do I probably have something else wrong?

Thanks for any advice you can give me!

73,
Jim WB5UDE

"elsie" by a WB6??? is pretty good for small filters...a demo version
will do 3 or 4 stage filters. Search the 'net for elsie+filter and
you'll probably find it.
Elsie=L-C...get it? pretty cute...but a totally cool program

The spilt driven would be the more simple method. You could build something similar to a dipole in the middle then use latter line to feed that into a balun then coax into that.

There is plenty of DOS left in Windows, just make a boot disk!

Well, you address several good topics here....Here are a few suggestions:

I would recommend getting rid of the proto-board. Build the ckt up 'dead-bug' style over an unetched copper plated (single sided) PC board. My experience suggests this is the single most important factor when working above a MHz or so.

If you have a scope, look at the output wave form with as much resolution as your scope can make to see if you can get a glimmer of the wave shape. Use a 10X probe if at all possible. Sometimes LC oscillators end up with way too much feedback and produce a really ugly wave form. ;)

Follow the osc with at least one stage of buffering. Use a 10-100 Ohm resistor in series with the positive voltage feed to each stage and put a .01uF cap to ground from the end of the resistor that goes to the ckt. Use a scope to check this wave shape as well.

Shielding is a wonderful thing but I get the sense that that is not the main problem right now. You might want to mount the variable cap behind a panel (another piece of PC board material), to cut down on the hand capacity effect.

BTW, I have built several converters of the type you mention feeding AM radios. They can offer very nice performance when teamed with a good BC set.

Let me know if you would like me to elaborate on any of the above.

Good luck and happy oscillating. :)

It has been my experience that no shielding is needed if this is a superhet design. However, solderless breadboards are nasty for RF. I build my homebrew radios using a combination of deadbug and small "nibbler tool" pads as needed right on the PC ground plane. Every power connection is bypassed to ground using small 0.1 uf ceramic bypass caps.

Deadbug style is great for prototyping. If a circuit does not work out, it can be unsoldered and reworked with a different circuit, and the parts can be reused. I do this frequently, even with the deadbug mounted ICs.

Some VFO topologies can tend to operate on more than one frequency at once, and the solderless breadboard will not help the situation. My favorite VFO is a Hartley using a FET and a tapped VFO inductor for feedback. It seems to be both simple and effective. You can probably find several examples of this in the ARRL handbook.

If your design is a direct conversion, shielding can be useful to keep the VFO signal out of the antenna and self detecting its own noise. In addition, if you use the same VFO for transmitting, the transmit signal can get into the VFO and cause it to pull, producing an undesirable chirp.

A simple shielded box does well for this. It does not have to be really elaborate. One suggestion might be to use an Altoids mint tin. Cut a section of PC board to fit inside the box and build deadbug style on top of this. It may or may not help to solder the lid shut in a couple of places once you have it all tuned up. Since it is steel, 2% silver bearing solder would make this step easier. Make sure you bypass the power that goes into the box. You might try a bypass cap to ground on both the inside and outside.

Good Luck!

Source record: 39415

I concur with all Dan's advice, including his choice of oscillator circuit. I highly recommend using a diode from gate to ground. It provides fixed and predictable limiting, and greatly improves temperature stability. Rohde and others have commented that this degrades oscillator noise performance, but it's nowhere near a noticeable level in a straightforward superhet or DC design. If you're designing a PLL where oscillator noise is greatly amplified, the diode might not be a good idea -- but then temperature stability isn't such a problem, either.

While VFO shielding doesn't seem important in a superhet, I've found that BFO shielding can be very important. When designing an AGC, I found BFO leakage to be a real problem -- it was much larger than the signal, and it was keeping the AGC biased up. Careful BFO shielding coupled with going to differential stages for the IF resulted in negligible problems with BFO leakage. And the sweetest AGC I've ever used.

> I am designing an extremely low power (<<1 W input) AM transmitter and
> have encountered several difficulties including how to determine the
> impedance of the modulation transformer.

Hi Joel,

I think you will find it is like driving a lightbulb (lamp). A car battery, for example, has a low output impedance (ca: 0.01-Ohms) but it drives a 12v 1A lamp (ca: 12-Ohms) without showing any "sagging".

If you are modulating a PA with AM, then you need to have a peak-to-peak AF waveform that is almost twice the supply voltage, AND the PA load (impedance) should NOT cause the voltage to "sag" (distort).

If you have a 12v supply to the PA and the modulator then the peak-to-peak output voltage from the modulator must be 24v, that is, varying from 0v to +24v. In practice it should be a little less or you will be overmodulating. If the PA was a 1-watt transmitter then you theoretically only need 500mW to modulate it. If you had an AF amplifier that would deliver, say, 2-Watts, then the PA will not be pushing the modulator to the edge of it's capabilities.

An Auto-transformer (eg 12-0-12v AC mains transformer) will do the job, even though it is for audio. Connect the 12- to the DC-12v supply and the -0- terminal to the modulator. The -12 terminal is the 12v supply to your PA stage. The AF stage cannot deliver more than the 12v supply, in fact it will be somewhat short of this due to losses in the output pair. It should not be possible to overmodulate with this arrangement. The AF output stage will only draw as much current as is required by the load, just like the battery/lamp earlier.

4356. how to double frequency at output of a wobulator?

Newsgroup: rec.radio.amateur.homebrew

Hi,

I picked up a R&S Polyskop 2 for 200 Euros and aftr a minor repair it works as designed up to 1.1 GHz.
Apparently with a mechanical mod in the wobbler cavity I can get it to cover 1296MHz too. (still have to get the details)

My question: How could I extend it's range to 2,4GHz after that?
I wonder if doubling the output frequency and using a appropriate external detector head instad of the built-in detector would do the job

Anyone who would have a valid hint on how to double the frequency on a range between, say, 1 to 1,25 GHz more or less linearly?

Thanks

Johan
P.S. needless to say, if I had either the money for playing or nearby friends to assist me in building one, I'd have a spectrum analyzer for years now.

Mini-Circuits do a doubler for this frequency range.....if you have enough output, you could split the signal and feed it into the LO and IF terinals of a mixer and HP filter the o/p then use an external attenuator. You would probably have to use an external "leveller" if you want that facility.

I'm in the process of retiring (modest budget) and hoping to do some HF and VLF antenna work. I have a Palomar R-X noise bridge that has served me reasonably well but it doesn't go below 1 mHz. I've used a borrowed MFJ 259 and Autek RF-1 but not enough experience to make a decision other than they sure are convenient. I've reviewed the Dec. 87 QST article on a Lab-Style RX noise bridge as well as the Aug. 89 QST on Improving R-X noise bridges by using a binocular ferrite core for the transformer, the "heart" of the noise bridge. I'm looking for intelligent opinions on what I should consider for my last or next to last antenna bridge. Right now I'm sort of leaning to building the Lab-Style in Dec 87 QST substituting the binocular ferrite core but I'm not sure what it'll take to get the instrument down to VLF and maybe LF, maybe two instruments or a band switch.. Have there been any articles elsewhere that I should find and read? Are there commercial instruments perhaps by HP or others that might be on the used market and should be considered?

4362. Stub-line Transformers. New program.

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-12-11 15:56:51 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <at7n83rjd4@sparta.btinternet.com>
Source record: 39426

NOW AVAILABLE

New Program " STUBTUNE.exe "

This program assists with the design of stub-line transformers used for such purposes as matching the feedpoint impedance of balanced radio antennas to the Zo impedance of the transmission line from the transmitter. This program is applicable only to balanced-pair lines. Transmission efficiency theough the transformer is calculated.

It is an improved version of program STUMATCH.exe in that it takes into account conductor loss in the transformer and is therefore more accurate when extreme ratios of (Antenna Impedance)/(Feedline Zo) are involved. Operating procedure is more complicated than STUMATCH. However it performs calculations beyond the facilities offered by the Smith Chart,

The program is peculiar in that the Zo of the feedline is not entered. All input data is variable in small up/down increments until the input impedance of the transformer is equal to the Zo of the line to be matched. Educational.

STUBTUNE is self-contained in one small file, download in a few seconds from website below, run immediately.

>Elsie=L-C...get it? pretty cute...but a totally cool program

"LCie" is a shareware program released in 1996, written and
copyrighted by Leonard H. Anderson. It will synthesize any
conventional L-C lowpass, highpass, bandpass, or bandstop
Butterworth, Chebyshev (choose your passband ripple in db),
or one type of Elliptic/Cauer response shape. It also
synthesizes relatively narrow "resonator" bandpass filter
values having high- or low-level coupling, capacitive or
inductive. It will draw a little diagram on an ASCII text printer
for the values.

"LCie" also analyzes filter response, either output amplitude
in db with relative phase ange and group delay or input impedance
or admittance with/without source resistance loading. Individual
values can be modified as desired and Qs set for finite values.
"LCie" can do sensitivity runs of input/output characteristics with
specified L and/or C variations within a given tolerance, plotting
the min, max, and average characteristics over frequency.

Sorry, didn't complete the message...

While LCie is indicated as shareware, I'm not looking for any fees.
If anyone wants an LCie package in a private e-mail attachment,
just write and its on its way. Free.

LCie works fine in any MS DOS, DOS 7 supplied with Win95 and
Win98 don't accept the command menu colors (works OK in
MS DOS 6.22). Microsoft stopped supporting their FORTRAN
shortly after I released LCie, would not explain why MS FORTRAN
DOS statements aren't all compatible with DOS 7. Calculations
and value results are still as accurate as before.

LCie's documentation includes some practical tips on filter
design.

Typically, for a 14-16 charge time I believe they usually charge at about 10% of the Amp Hour rating of the battery (which is what most wall warts supply that come with the handheld), so in this case if you build a charger that puts out a constant current of about 80 mA, you can leave the charger hooked up indefinitely. I's think thats about how it works. Nicads need a constant current source, not a constant voltage source like a DC power supply puts out. Maybe you can find the right charger for the HT on ebay...

Legal? Licensed or unlicensed? Trying to extend the range of those 2.4 GHz video camera modules? Probably not legal to boost it.....Now, if it operates somewhere in the ham band up there, that's a different story! There are a few places that sell amplifier brick amps, but they're not cheap! Maybe try Down East Microwave at
http://www.downeastmicrowave.com/

I have found RFSim99 a VERY powerful program. It is an S parameter simulator with schematic entry and you can also do a Monte Carlo style tolerance analysis.

I've imported quite a few devices as S parameters so adding new devices is pretty straightforward.

It was a completely free program offered by Hydesign.

I have not been able to get to the Hydesign website for quite a long time, maybe a year or so....

Still, the program is avaliable free many places on the web.

Well i have an old world radio made by Triumph or that may be the model... I've occasionally been able to pick up cw and ssb on it with some help from my Little Pixie radios..

I was wondering if anyone had schematics for this particular radio. I'm wanting to change the sw1
band so that when i tune it will only cover the 40 meter band. as it is right now 40 meters is only a small portion on it's tuning for the sw1 band.

I've done a search through google and on the web and only found for sale pages.. I've also considered using the radio for parts as it has a lot of nice caps and other parts... but it is working and would be a waste to ruin a working product. :)

MMICs from a couple of manufacturers such as Mini-Circuits, RF Micro Devices (RFMD) should fill the bill. Cost is around 3USD.

I don't know the particular radio so maybe you could describe it or
provide a link???
In most radios that have say a 6-18 MHz SW range it is because they are
using the same main tuning capacitor as is used on BCB only with a
different coil to raise the frequency. The 'cure' is to change the
tuning cap to one with a much smaller range but that may necessitate
changing the coils, etc.
The tuning cap for BCB is typically on the order of 20-365pf for the RF
section and something like 12-260pf for the local oscillator section.
Now lets assume for this example that your SW band is indeed 6-18
MHz...that would mean that the 7 MHz portion might be only using
something like the 300-320pf portion of the RF section range and
220-240pf of the Oscillator section range.
In an old tube set you can yank out a bunch of the plates and get
something like the 0-20pf result indicated and use a fixed capacitor to
make up the overall difference.
In a transistor set with the little tiny tuning cap, forget it.
So, suffice it to say that yes, it could be done with an old tube set
with a sufficient amount of tinkering and an understanding of how it works.
However, once you did, the next question might involve the drift and
stability.
If the set has any resale value at all, a better option might be to
unload it on ebay and buy one of the little single-band receiver kits!

Good luck,
Bill

I'm with Bill- why start tearing up a classic, only to end up with a mediocre performer? Build or p/u one of the 40M kits on the market. Leave the old girl alone.

Well its a transistor model i figure one of the earlier ones as it's got the number of transistors labeled on it like a selling point.. Covers 7 different ranges.. LW 150 -350kc
am
Marine band 1.6 -4.5
sw1 4.5 to 12 mhz
sw2 12 to 24 mhz
fm
and air 108 to 174..
As far as selling it i don't think that i could part with it is nice and does pick up local civil services so it's definitely not going to the parts bin just yet i was just hoping to get the schematics to figure out weather i could make a simple mod to adjust one of it's tuning ranges or weather it would effect the whole radio. As it sounds changing the caps would definitely ruin it's usefulness on the other bands and wouldn't be worth it..So like you say maybe i should just leave well enough alone and buy some other kit to keep my occupied.

4382. ARRL Freq Msmt Test revisited

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-12-12 18:26:58 UTC
From: k7itm@aol.com
Message-ID: <3200347.0212121026.3e3a7c89@posting.google.com>
Source record: 39445

Since submissions to the ARRL frequency measurement test were supposed to be postmarked by 6 December, I guess it's OK to post my results. I used a pretty terrible antenna, and didn't hear anything at my location a bit N. of Seattle on 3.5 or 21MHz. I reported 7,046,882.23Hz +/- 0.5Hz and 14,049,083.6Hz +/- 1.0Hz for 40 and 20 meters. (The tolerances come from spectral spreading by the propagation for the most part.)

Anyone else?

Cheers,
Tom

Tom----here's what I submitted:

80m -- 3579335.0 Hz (although I just looked and saw that I mistakenly marked them as "kHz" ooops), and

40m -- 7046882.6 Hz

I couldn't get any reliable measurements here in Virginia on 20m and 15m. League rep told me on Tuesday that the results will be posted soon as an article on the web page and that each participant will get a letter before Xmas.

Possible? I'm not going to say no because I've learned that
anything is possible, if one is willing to throw enough money and effort
at it.

Desirable? Hardly. Remember that a TV tuner -- ANY TV tuner -- has
a per-channel bandwidth of 6MHz. Given that the typical bandwidth of even
an SSB transmission is around 6KHz, well... I think you can see where
that's going.

> With book tree chips?

Who the heck is "book tree?" Are you referring to Brooktree?

In any case... Not worth the effort. If you want to listen to 2
meters, pop over to Radio Shack and pick up a scanner. If you're licensed
for that band, and you want to do more than listen, there's plenty of
cheap/used 2m rigs available both at retail and on Ebay.

True, however the sound (FM) bandwidth is around 50KHz. A fair amount of the 2m transmissions that would be picked up are FM. The s/n ratio will not be all that it could be and the audio output may be a little low but it can be done. I have an I2C TV tuner I'm playing with and have no trouble listening to the local 2m repeater using a standard TV audio IF strip. I may be wrong, but is not the usual bandwidth of an SSB transmission in the region of 2.5-3.0KHz ?

You CAN copy 144 MHz signals just like 88-108 FM and 152-174 Two-way, etc.
The bandwidth in regard to receiving the whole band 144-150 Mhz at one
time is the obvious issue because you have no means to select one single
station if there is more than one. You will be dependent on 'capture
effect' so that only the strongest signal(s) come through.
The other issue is the noise bandwidth of a 6 MHz wide receiver versus a
normal 15-30 kHz wide receiver. The result is very poor sensitivity for
such a narrow signal.
But, yes, if the signals are strong enough you can receive them.

First, the IF filters determine the bandwidth of the receiver, NOT the
frontend.

Secondly, many TV cards use the intracarrier technique which beats the
visual and aural carriers together to produce the 4.5 MHz sound IF.

The answer is no.

says...

> yes but why can you copy fm stations from 88-108 with a pc tuner????

The fact that the tuner is mounted in a PC is utterly irrelevant to
the design of the tuner. If said tuner is designed to pick up FM
broadcast stations, it will do so.

> i can see where it's going.....(to a point) ok fm stations are wide.....but
> its not 6mhz........

I should have made myself clearer. I believe it is physically
possible to copy 2m stations with a TV tuner based device. HOWEVER --
what I was getting at originally is that, assuming you can convince the
card to even tune those frequencies, the selectivity and adjacent-channel
rejection numbers for such a device would be horrible for narrow-band FM.
TV and FM tuners are, by design, broad as the proverbial barn door.

With a TV tuner, you'd end up getting the whole 2m band at once,
plus 2MHz of the commercial band either above it. An FM broadcast tuner
wouldn't be much better, with its 100KHz-per-channel spacing. The only
thing allowing you to hear a single 2m station with either device would
FM's characteristic 'capture' effect.

You're far better off using a scanner or 2m rig -- something that's
designed from the ground up to do what you want to do.

Absolutely correct, and I should have pointed that out in my
original post (sound of palm hitting head).

> Secondly, many TV cards use the intracarrier technique which beats the
> visual and aural carriers together to produce the 4.5 MHz sound IF.

Thank you! This was the factor I had forgotten about.

Virtually identical to what I found in southern CA,Tom, which is not really surprising. I still maintain that it is relatively easy to measure frequency off air to with 1/100 of 1 Hz but that ionospheric spreading is often around two orders of magnitude greater than that for other than local stations. I even see what looks like a steady error of nearly a whole Hertz on WWV round local dusk and dawn at times, as the effective path length changes.

An interesting excercise though. Maybe next time I'll get the BC221 out of the garage, now that would be fun!

>But, yes, if the signals are strong enough you can receive them.

As far as I know, the TV cards demodulate the TV signal down to video
baseband and is then going through an A/D converter with 8 bit
resolution.

A typical TV receiver will determine the a.g.c. voltage during the
synch tip. If there are no synch pulses in the receiver bandwidth, the
a.g.c. might not work.

However, if some form of a.g.c. will be generated, it most likely will
set the receiver gain so that the signal envelope will fit within the
ADC range. If there is a strong signal within the 4-6 MHz video
bandwidth, it will dominate the ADC range. With only 8 bit resolution,
the ADC dynamic range is only 48 dB, thus any desired signal which is
48 dB or more below the strongest signal in the video bandwidth would
be less than the LSB bit. Fortunately, the dithering effects will
permit recovering some information even if the amplitude of the
desired signal is below the 1 bit LSB amplitude.

Anyway, the narrow band FM signal would have to be extracted from the
digital stream sampled at about 13 MHz. This could be done by building
a bandpass filter running at the 13 MHz sampling frequency. An other
approach would be to multiply each "video" sample with a digital sine
wave carrier close to the desired signal, then low pass filter it with
a filter running at 13 MHz sampling frequency. The resulting
difference frequency can then be processed at a lower sampling
frequency to digitally demodulate the narrow band FM carrier.

While the extraction could be done if sufficient computing power is
available, the resulting dynamic range would be very poor due to the
analog a.g.c. and the 8 bit video ADC resolution.

Hello folks, I know that this is slightly off topic, but since many of you have Drake equipment, I have decided to post in this area.
I have manuals for Drake equipment in PDF form. These would be for the 1A, 2B, 2C, R4A, R4B,R4C,
SPR-4, SW4 FS4, R7, R8, TR3, TR4, TR4C, T4X, TR6,TR7, UV3, MN2000, and other tuners. Also, I have the '7 series owners and service manuals, along with manuals for the RR-1, MSR-2, etc.
Price, including shipping in the USA will be $18.00 for each manual. In cases such as with the TR7, I will include both the Owners Manual and the Service manual for that price. With overseas customers, we will need to discuss shipping first.
Any interested parties can e-mail me directly.

Hi Jordan

I built this one for charging gel cells but it should work fine for nicads.
http://www.rason.org/Projects/gelcell/gelcell.htm

I use a 20v laptop supply for my voltage source. It works great.
I am going to put a 10 turn 10k pot on the front panel so I can vary
the voltage for different batteries. Right now I have it built as
described.
I have designed a circuit board layout. If you are interested contact me.

Here's another link that might be useful.
http://wiredworld.tripod.com/tronics/batt_chg.html

Good Luck!

I've recently bought an electromechanical filter, hope it's a bargain. It's got written on the top: "42" - bold and big font, "Type: 450A-32" - guess it's 450kHz. My question is: what is the bandwidth and output/input impedance. The filter is frequently met in russian transceiver constructions, looks like a metal can 6x1.5x2 cm with 4 legs (2 input and 2 output). Thanks for any info!

Source record: 39313
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.antenna,alt.radio.amateur

I've got a SignalCrafter model 30 SWR Power meter and would like to find another in working condition, or another SWR/Power meter with similar features.

The SignalCrafter Model 30 has two meters. The lefthand one displays Power in three ranges, 20W, 200W, and 2000W. The righthand meter displays SWR, and under the SWR scale is something they called reflection coefficient. It also provides the ability to switch between three antennas and a dummy load. I don't care about the switching for antennas, as I only use mine for a SWR/Power meter, and use a different custom switching array for my antenna switches.

The SignalCrafter Model 30 was made in the early 80's and is an ACTIVE SWR meter. There is no "set" knob or need to mess around with anything other than the switches that select the power level. It's operation is very similar to the dual panel meters that are built into the JW Miller AT2500 Antenna Tuner of similar vintage.

Does anyone know of the availability of a SignalCrafter Model 30 or similar unit, or have a schematic that could be used to modify (add circuitry) to the existing cross needle swr meters in my MFJ Differential T Tuners? I really dislike the cross needle meters that require you to interpret the swr by reading a red line where the needles cross. I can pretty easily make a new dial scale if I can get a schematic to build the active circuitry to drive the meters.

Thanks

well, I had the large old Polyskope covering up to 1200MHz, but the
problem is when you operate it in populated areas, you probably block
all the TV channels. So it is better idea to buy some modern VCO's
from Mini-Circuits and use as little as possible of the old stuff

If it is anything like the collins markings, the 32 probably means 3.2
kHz.
If it was intended for tube circuits and resonated by external tuning caps
it is probably fairly high impedance in the parallel tuned mode.

Source record: 39316

:-) I used a couple of old prototype HP3588 spectrum analyzers, one on 40 meters and one on 20 meters, locked to an HP10811D oven oscillator reference. Those analyzers use digitization, decimation, and FFT techniques to get down to very narrow resolution bandwidths (a few millihertz minimum). I used 0.35Hz resolution bandwidth for the measurements I made. The propagation conditions didn't deserve any better than that. Even though I used that RBW, it's quite possible to resolve much finer increments of frequency from the same length of measurement, because the effective filter shapes are known quite accurately, allowing interpolation. I'd agree with Dan that resolution down to better than 0.01Hz is straightforward, given a clean signal. But some of the samples from the FMT evening were spread out quite badly.

WWV, around sun-up or sun-down, often splits into two distinct peaks here, presumably one for WWV and one for WWVH. Like Dan, I've seen shifts of 1Hz and greater on 10 and 15MHz.

Cheers,
Tom

I presume those shifts can only b due to Doppler spreading caused by motion of the ionoshpere at that time. Are the amounts of shift plausible?

Keith

I'm not an expert on the 130, but sometimes when you drive the finals on a rig a little too hard they go into a mode of oscillating on multiple frequencies, often with lots of output. The output filtering can't whack out these high levels of spurs so the output is rich in spurious signals. Of course, with plenty of frequencies in the output, no amount of twiddling the antenna tuner can bring about a match. I suspect if this is happening, and you look at the output on a fast scope (probably lots of the spurs are very high frequencies) you probably aren't going to see a nice sine wave.

..

Tom's set-up is a little more sophisticated, but I was using a Racal RA1792 receiver, the frequency measuring version with 1 Hz readout, that has a 100 KHz IF output, in which all the oscillators are derived from a standard frequency. I was either using a Racal 9475 Rubidium or a Shera GPS standard, I don't remember. The 100 KHz ouput is fed either to a counter or to a double beam scope, with the other input fed from 100 KHz derived from the same standard.

This method of comparison, with the scope, is very useful, and can get very precise resolution over a period of time.

With the scope set-up you can see "chirp" on one of the W1AW Txs as it is keyed. It is les than 1 Hz, I imagine it is disturbances on the PLL control line

So ears don't really enter into it :^)

And, yes, observed shifts like that are totally plausible on the WWV signals. WWV is best mid afternoon local time, then you can get to within 1 part in 10 to the 8 with a bit of luck. My standards are around 3 orders of magnitude better than that.

dr

Source record: 39329

An "L match" is also called an L network and usually consists of an inductor and a capacitor.
It is used for impedance transformation or "matching".

A rough example...

If you want to match a 100 ohm source to a 1000 ohm load at 10 Mhz:

The network Q is the square root of [1000 / 100] -1.

1000 / 100 is 10 and 10 - 1=9. The square root of 9 is 3 which is the Q.

The series reactance needed is Q * Rs = 3 * 100 = 300 ohms.

The parallel reactance needed is Rp / Q = 1000 / 3 = 333.3 ohms.

Now just find the L and C that give those reactances at 10 Mhz.

L = Xs / 2 * Pi * F = 4.77 uH
C = 1 / 2 * Pi * F * Xp = 48 pF

This simplified method works best when the Q is around 5 or higher.
In the above example, the source and load are resistive impedances (R +/- J0).

There is plenty of reading material available to turn this molehill into a mountain if you need all the details.

In article <bicmvuso4v3h4l8889d14v5v79apvd7c8h@4ax.com>, Paul Burridge
<pb@notthisbitosiris1.co.uk> writes:

>What does an "L-match" consist of and how does one go about
>calculating what values of what need to be chosen to transform
>impedance x to impedance y?

An L-Match network consists of a series reactance and a
shunt reactance, the shunt on either source or load end
although usually on the load end. Such a network is good
only for a relatively narrow range of frequencies big enough
to accomodate 30 to 40 KHz span at lower HF.

A very quick way to find out values is to use available computer
programs such as Reg Edwards' nice little DOS executables.
Another way is to look in several countries' amateur handbooks
for value tables or formulas.

You can derive your own values by some simple algebra...and
prehaps learn a bit more about complex quantities at the same
time. That takes some effort, especially if one hasn't done that
since formal schooling. That procedure for finding the L and C
values for a pure resistive impedance at the source is as follows:

1. Transform the known load impedance into an admittance.
Just do a complex inversion of the impedance.
2. Add an unknown susceptance (represented only as a symbol)
in shunt with the load admittance. Admittances in shunt will
always add algebraically.
3. Do a complex inversion of this total to find a temporary total
impedance. Add an unknown reactance to this impedance
(only as a symbol, value to be found later). The reactance
will always be of opposite type to the shunt admittance (if
one is capacitive, the other is inductive).
4. The temporary total achieved thus far is a complex
impedance which represents "what is seen by the source
looking towards the load." What is known at this point is
the resistive and reactive values of the load and the desired
resistive value that the source "wants to see." Algebra is
now required to solve for the values of the L-Match unknowns.
5. It may help to find another equated expression...the total
impedance of the desired resistive source plus the reactance
in series, that equated with the inverted total admittance of
the load plus the added shunt susceptance. That yields two
equated expressions to help solve two unknowns.
6. The algebra takes some work even if experienced with solving

equations. That work should result in a conjugate match
where the added series and shunt network values "cancel
out" (reduce to zero) the load reactance...AND the impedance
"looking into the source" is entirely resistive and of the desired
source resistance value.
7. The magnitude of the total load impedance can be higher or
lower than the desired resistive value at the source end. The
Ls and Cs of the L-Match network will swap positions with
load-higher versus load-lower than desired source resistance.
8. An L-Match network can handle a wide range of load impedance
magnitudes, usually greater than 10 times source resistance to
less than 1/10th source resistance. [there are definite limits,
but the match range is exremely wide] With only two added
components they present the best on good power transfer
source to load. The network is effective at only one frequency
but works over nearly all amateur HF to VHF signal bandwidths.
9. A PC can find the exact values in milliseconds if programmed
correctly. Handbook tables and formulas exist. One has to
be familiar enough with complex quantities to tackle the
algebraic solution direct route. :-)

4418. RF 3.9MHz Booster amplifier

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-12-15 01:28:42 UTC
From: la8ak.xnd@online.no
Message-ID: <3dfbda1e.192718256@news.online.no>
Source record: 39333

Hi

My mobile boatanchor transmitter has 100mW output on AM/CW (from RL2P3 stage) and I would like to build a linear amplifier for 3.500MHz CW and 3.965MHz AM operation..

Available transistors in larger amount in my shack are SRF1191=2N5941 =MRF466, 2N6370 and IRF630.
The SRF1191=MRF466 has 26dB gain on 4MHz according to Motorola RF design manual (40W RF for 0.1W drive), but it is for 28V supply voltage, the car battery voltage is limited to max 14.4V, it is probably around 10W for 12V supply, so I wonder which type to choose, and I don't want to use a voltage converter for the PA (It is bad enough that the rig need 2V 1.5A and 150V 40mA).

Also have a lot of VHF and UHF power devices, they will have tremendous gain on HF, but are they tame? 2N6082 and 2N6084 have 19-20dB gain on 50MHz with 20W RF out.
Suggest using simple L-C-C input and output matching. MRF466 has 3.7-j1.45 input impedance.

Would like to hear your opinion about which device to choose for at least 10W RF o/p, instead of buying a new one

4419. Re: pi section harmonic filter software

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-12-15 01:30:03 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <uvnmou3bqtd1d0@corp.supernews.com>
Source record: 39332

There's a very simple filter type that's used very often for this purpose. It doesn't provide as much harmonic attenuation as some other filter types, but it's adequate for this purpose, is dead simple to design and implement, and is extremely forgiving of component variations. It's a lowpass pi network (input shunt capacitor to ground, series inductor, output shunt capacitor to ground) with each of the elements having a reactance of 50 ohms at the operating frequency. You can find the equations for reactance in any handbook, to calculate the component values. This particular implementation can be called a "quarter wave filter", since it gives the same impedance transformation at the operating frequency as a quarter wave transmission line. Two can be cascaded to become a "half wave filter" for greater harmonic attenuation. When doing this, the center capacitors are usually combined into one capacitor with twice the value (that is, the combined center capacitor has a reactance of 25 ohms at the operating frequency).

Filter design is a complex topic, involving a number of properties that have to be traded off against each other. The above approach is fast and simple, and, unless you need an extreme amount of harmonic attenuation with the minimum number of components and are willing to put up with a more critical design, is adequate for the purpose.

Hi,

I got:

3,579,334.6 Hz
7,046,882.5 Hz
14,049,083.2 Hz
21,069,675.4 Hz

Setup was a couple of receivers on each frequency and a sound card on each receiver. Everything was locked to a free running Rubidium. Even on ground wave there was significant spreading. I'd have to go back and look but I think it was something in the 1/2 Hertz range on all frequencies.

I was a bit surprised that I could copy W1AW better on 2 meters than on 15 meters. Antennas and propagation can be weird.

If the unit's bandspread will allow it to tune there without
degradation, then I may be able to program it for you (need to check and
see if I have the right cable).

You -really- don't want to go chasing copies of Motorola RSS
without buying it. Their licensing agreement is positively Draconian (I
know... I had to sign it to get my stuff started!), and their legal
eagles can and will make an example of anyone who they think is
trafficking in pirated RSS.

Anyway... http://www.bluefeathertech.com/rf.html -- Let me know via
E-mail if you want me to try programming that beastie.

Keep the peace(es).

From: Joe Leikhim <jleikhim@nettally.com>
Message-ID: <3DFC2296.89229A10@nettally.com>
Source record: 39339

Hi I am looking for a 1.000 GHz frequency source to drive a
downconverter project. The source needs to be low noise and be
referenced to an external 10 Mhz reference. It doesn't need modulation
and channel spacing is not important. What I am looking for is a board
with parallel address lines which can be either DIP switch or jumper
programmable. I know that Z-Comm has an eval board that looks promising
but it requires a PC to load the data into a latch. It looks volatile. I
don't want to complicate the project with a PIC just to load the
frequency which will always be the same.

See the Chebyshev LPF PI-Configuration table in most
(all?) recent editions of the ARRL Handbook.

Component values for a 3 element Chebyshev, 0.1dB ripple
LPF with component values normalised for 1MHz/50 Ohms.

C1, C2 = 3283.6 pF

L1 = 9.131 microHenries.

RFSim is a freeware program with some nice filter design tools.
You can get it at:
http://sharon.esrac.ele.tue.nl/pub/funk2001/Etronik/rfsim/RFSIM99.EXE

The serial data isn't anything to do with the eval board?
you are actually programming the device, if you use any
of those devices you will need to get data into them
Why 10mhz? why not a 300mhz tripler, wouldn't be that
noisy? say a balanced ring with a couple of Schottky dodes?

Maybe someone ahs already done this, and can supply a reference. My query is in response to on air comments tonight after a break of many years from HF operating - a junkyard TS440 I fixed as an exercise, an old junkbox CB mike wired to it. Received audio reports were OK, ie Q5, But "harsh" - obviously an unknown microphone, my voice is fairly deep, resulting in non optimum transmit audio.

Is it possible with simple test gear to
1. Plot the bandwidth/frequency response of ones voice
2. Tailor the microphone output response to match this curve.

Any comments appreciated.

Usually these backlights are integral to the LCD, so not replaceable.
However, the integral backlights are almost always LED, so wouldn't go dark
all of a sudden. If it's an LED, I would expect the problem to be in some
regulator or current limiter external to the LCD itself.

Sometimes they are backlit with an electroluminescent film. These are
replaceable, but relatively expensive. Once again, though, I would look for
an external part to be the culprit.

Of course, it is possible that the LCD is lit with incandescent bulbs, in
which case a replacement is pretty feasible. Most likely you could tell
from the color the backlight used to be whether it's LED (green or yellow),
electroluminescent (blue or cold white), or incandescent (warmer white).

Since you probably don't have a schematic, it may be cheaper, and a lot less
hassle, to run down to K-Mart and pick up another radio. The main problem
with that approach is that the features on the $500 flavor are going to be
awfully tempting!

That vintage, I think electrolumenescient is unlikely.

The big problem you will run into is the classic "$1 part, $100 labor
problem". The part will take a bit of effort to get to. A Toyota would
be my first stop on this, if nothing else, they may have a manual you
could look at or a mechanic who could size up the job from having done
it before.

Happy trails,

Are you saying once I program their (Z-COMM's) PLL with their PC based loader I can remove power from the circuit and it will retain the frequency data? If so it will work.

> Why 10mhz? why not a 300mhz tripler, wouldn't be that

I guess I could do that but I want the LO to be locked to the 10 MHz reference of the host equipment. So 1000/10 is a lot of multiplication and possible spurs.

Mostly they use incandescent bulbs because they are very cheap. Rip the top
off the radio and see what's in there. You'll never know unless you look.

The backlight is usually a grain of wheat incandescent bulb guided
into a light pipe (big chunk o' clear plastic). The is probably 4-6 of
them that light the whole front panel of the radio.

You can probably get by with a BS-1 (Basic stamp). If you can ensure
power, you could use a PC.

Other options would be to use a parallel to serial bit loader, or
replace the serial PLL chip will a parall load one.

From: Jim Pennell <NoSpam@killspam.com>
Message-ID: <ativ7c$6ia$1@slb9.atl.mindspring.net>
Source record: 39355

Pretty much all of the "one chip" pll devices these days will require serial programming whenever you apply power.

However, for a fixed frequency synthesizer there are quite a lot of simple ways to program it. A basic stamp would do nicely or even a 555 chip feeding an EEPROM to clock the data out to the synthesizer.

Using a 555 to clock a serial EEPROM is about as simple as it gets, and it should work nicely. Something like the 93c56 serial EEPROM.

==========

However, the question of phase noise is a different problem. Most PLL synthesizers at 1 GHz don't have great phase noise. Another question is, how quiet is the 10 MHz external signal you want to use as a reference ?

Depending on what's more important in your design, phase noise or ease of circuitry, you have two major choices.

Personally, I'd be tempted to make a 100 MHz VCXO that is multiplied to make 1 GHz.

True, multiplier feedthru and such can be troublesome, but if you start with a balanced doubler, you can get 200 MHz and suppress the 100 MHz and 300 MHz undesired.

So then an X5 and the nearest undesired outputs are 200 MHz either side of the 1 GHz signal.

You can, of course, make a fairly simple phase lock for the 100 MHz to the external 10 MHz. If you use a narrow loop filter, it'll clean up the signal from the external 10 MHz.

Admitted, this is extra parts for the design, but it is a much lower phase noise approach than using a PLL board and locking a 1 GHz VCO to 10 MHz.

You could look at

http://www.qsl.net/ke5fx/

The DDS/PLL board may be a bit of an overkill, but you could omit the DDS
and simply drive the PLL with a reference.
Most if not all PLL chips will need some programming to get them going and
most will be serial.
I think Hugh VA3TO was looking at getting some boards made up.
If you want best phase noise performance it might be better to multiply up a
crystal source using doublers/triplers

Richard

You could try looking at the "gain vs Freq" charts, provided in the
databook (at least in my Motorola book).
Often a chart of "Max Gain vs Freq" is included.

An MRF134 is good from 2mHz to over 400mHz, at 5W Po.

Well I've tried it and it wasn't that simple, I don't know the
93c56 but I've used the 24c16 to do a similar job and that
required a series of codes before it would clock out.
also this has got to operate at switch on, again my experiance
found that it was quite tricky to reset everything and get it
to clock in reliably every time, not saying it can't be done
but I don't think it will be a breeze..
I agree about the noise, unless this is a VERY special sort
of application I can't see the VXO/xtal generator not being
suitable
Also there other eval boards, Maxim-IC do some.......

While I've seen some good suggestions from others, here's
an alternative that does not require programming. With just
one frequency at all times that is an exact decimal multiple
of a reference, a solution can be all in hardware, most of it
using DIP ICs:

1. A VCO at 1 GHz (such as available from Mini-Circuits)
with a splitter for output to the converter and to a digital
divider chain. The divider chain would be -
2. A 1 GHz-capable divide-by-10 that would output 100 MHz
to another divide-by-10 that used high-speed Schottky or
equivalent internals (ACT, FAST, etc. families) whose
output would be 10 MHz to -
3. Three CMOS logic divide-by-10 ICs in series to result in
10 KHz to input to a phase-frequency detector IC.
4. Another trio of divide-by-10 ICs to achieve the 10 KHz
phase-frequency detector reference input from the
external 10 MHz standard.
5. The phase-frequency detector can be an integral IC such
as the now-rare Motorola MC4044 or made from three
NAND gate ICs connected in the same configuration.
See Ham Radio magazine, September 1982, "Inside A
Phase-Frequency Detector" for the gate configuration and
waveforms at each PFD gate output.
6. The Loop Filter from PFD output to the VCO is straight-
forward, one frequency and one tuning rate (of the VCO)
and may be calculated by formulas found in many PLL
references and application notes. It is passive. From
typical Mini-Circuits VCO tuning rate specifications, the
PFD output voltage swing with 5 VDC supply rail should
be compatible and not need level shifting with an op-amp.
[check that before calculating the Loop Filter values]

A phase-frequency detector has intrinsic limits of its output such that if the signal input is well away from the reference, its output will remain in a limited swing to force the VCO back to proper frequency. Since only one frequency is to be locked, the location of possible spurs is known ahead of time...the PFD detector inputs could also be 100 KHz to reduce the divider chains yet would have only a minor effect on PFD output voltage-versus-phase characteristics compared to 10 KHz.

There still exist some dual divide-by-10 ICs that accept 10 MHz inputs. Using those would reduce the can count.

About the only foreseeable problem possibility would be the 1 GHz split and its strength to drive the very-high-speed decade divider without "skipping" count states. A small buffer amplifier might be needed. If the buffer amplifier has a differential output, each output could be made to inputs of a dual 2-input NAND connected as a set-reset flip-flop; that would insure the FF output is squared off and to acceptible digital levels required of the very-high-speed divide-by-10 (commonly used as a "prescaler" in TV PLL tuners).

None of the above is as elegant as a single-IC System On a Chip ("SOC") with everything in one package. It does avoid any need for fussing with a serial data input to the SOC in order to set the single locked frequency. It's an alternative wired-in configuration not needing programming.

> output would be 10 MHz to -

People made PLL's with your solution before programmable ICs, and
the concept is still as valid.

What I'd add is that maybe there are better choices than a decade
divider at the front. We'd see those common in the days of frequency
counter articles, but they seem fairly invisible nowadays.

More common are some power of two divider. It would require some
shift in the rest of the counters, but these might be more available.

I haven't kept track of frequency limits so maybe some or all of
these suggestions are invalid, but here are a few places I'd check.

Digitally tuned TVs and cable converters (and VCRs) would have prescalers
that would probably drop the input frequency by quite a bit more than
a decade. I suspect, though, that these would be pushing their upper
limit at 1GHz.

Older cellphones (older because they have more recognizable parts and
probably larger parts) would have prescalers, which might work to 1GHz.

If those don't pan out, I suspect still that finding something that
divides by 32 or 64 might be more available than a divide by 10 at
this point.

If the original poster could get by with a 500MHz signal that is
doubled, either of the above sources would likely supply a suitable
prescaler.

Grab 'em up.

1 MHz isn't a real common frequency. DigiKey has 'em, but they want $17.88 for a 1 MHz crystal in and HC49, $0.64 if you want 4 MHz, same specs, manufacturer. DigiKey has crystals from a half-dozen manufacturers and only one has a 1 MHz flavor. All the others have a gap between 149 KHz and 4 MHz in the smaller (C) sizes, 3.979 MHz in the larger (HC) sizes.

As Dick points out, "smaller" is a relative term. The big old FT-243's are pretty hard to come by these days. HC49's and HC25's are the sort of crystals you will find in HT's and the like, about 5 x 11 x 14 mm. The C-2 or C-301 size is a teeny cylinder with very fragile leads. They are a lot smaller than the HC units (3mm diameter by 9mm long), but you need to be pretty careful with them. There are also a passel of surface mount sizes, but most of them are similar in size, or even larger, than the C types.

Of course if Dick wants twenty bucks for them, maybe you want to have International make you one. When you get into that neighborhood might as well go to the experts and have them make exactly what you want.

Personally, I would divide down a 4 MHz rock if I had the flexibility.

Hate to be the practicle damper on this but been there and most
of these old prescalers are unreliable at 1g and the only way to
get round the problem is more volts and then they get hot!!
not only that but the layout and pcb around the chip become
critical, again can be done but not easy....

4454. Capacitor ESR meter ?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-12-16 23:30:25 UTC
From: Henry Kolesnik <wd5jfr@oklahoma.net>
Message-ID: <uvsogn51mm3a7a@corp.supernews.com>
Source record: 39367

Has anyone used the ESR meters by Dick Smith for $50.00 in kit form or the CapacitorWizard at $160.00 vs using a sig. gen. and a scope? Is the CW worth the extra money for casual testing of incircuit ESR of electrolytics and possibly larger value paper capacitors?
This site has an excellent comparison:
http://www.anatekcorp.com/testequipment/esrcompar.htm

but I'd like some user non-commercial opinions. Do they really find the bad capacitors that cause the equipment to malfunction or do they lead you to replace a bunch of marginal capacitors that are probably OK in that particular circuit. I've got several pieces of bad test eqpt that I'm sure have bad and marginal caps but I don't want to waste my time replacing marginal caps. In some cases I would be shooting in the dark using an ESR meter at times as I don't have schematics on some of the equipment and some schematics take a long time to find at a reasonable price.

tnx

I hunt for dead caps with a square wave generator, CRO and a 10K
resistor. If the cap can't shunt most of the signal, it's stuffed.
Marginal cases are where more thought is required, it depends on what
the device is actually doing in the circuit.

Electros are cheap, I usually just replace any that are suspect, it
doesn't take long, you only need to turn the board over twice and do
them all in one hit.

If it is swollen, replace it, no matter how good it tests.

I bought and assembled a Dick Smith ESR kit and was fully satisfied with the performance. I went through my capacitors and found a number that appeared to be ok on a Fluke meter (i.e. getting a capacitance reading) but were out of whack on the ESR.

As well, the help I got from the inventor/designer after was super.

it works and I don't regret buying it. Instructions are clear and assembly skills require normal soldering skill.

pretty much correct , the 120 was even worse . a good clean of the earthing pads and addition of a good ground strap should sort it , although you may need to tighten the alc a little also on the higher bands..

Hello Hank,

I haven't used either the Capacitor Wizard or the Dick Smith meter but, having looked extensively at the options recently I ended up building one to a design published in the March and April 99 issues of the UK magazine Television. This uses 2 ICs and a handful of discretes (as well as the meter movement) for the ESR meter and a further IC to run a buzzer which sounds when the ESR is below about 1 ohm. Total cost was around $5 (the meter movement cost me ?0.50 from a flea market) and the thing seems to do as good a job as the commercial kits. If you want the circuit let me know via the Email address below (remove the don'tspam).

You might also like to look at
http://www.qsl.net/iz7ath/web/02_brew/15_lab/06_esr/index.htm

where IZ7ATH gives details of a similar low cost design.

So use a new one. :-)

I typed "prescaler" in to Digi-Key's web page and got
a page full of hits, almost all useful for such a project.

The first hit was the NEC UPB1506GV, good to 3 GHz,
division by 64, 128, 256. In stock, available in onesies
and twosies for 3 bucks.

Alternatively, use one of the available microwave LO
boards, like the Downeast Microwave or G4DDK units.

Good suggestions, Laura. There are a number of
"prescaler" or high-speed dividers still available on the
market. The ones I'm familiar with, used, proven
successfully two decades ago are Plessey ICs which
are no longer in production. Today's choices are
oriented towards division by powers of two...which is
not a problem for a fixed divider.

The original thread started with a desired single-
frequency output at 1 GHz which was desired to be
locked to an external 10 MHz reference frequency.
There are many different ways to do that, including
some that weren't mentioned (sampling types with
auto-search on unlock, common in industry use in
1970 for microwave sources).

Some others have commented on "decade" division
but that is NOT any sort of absolute in division to
lock to a reference. All that is required is a division
of both source and reference to achieve the SAME
frequency of input to the phase detector in a PLL.
Decade division was mentioned as illustrative only,

for the purposes of explanation. The original message had a fixed 1000 MHz source and a 10 MHz reference. The ratio of those is 100:1 and the 1 GHz source need only be divided by 100 more than the reference. 100 factors to 2*2*5*5. Other dividers on both source and reference could be exactly the same binary, decade, or whatever is an integer number. From there on, the division is picked to fit a phase comparator input frequency and the loop filter values. With a single fixed source frequency the loop filter calculation is simple, no worries about fitting values to match variable division and/or non-linear VCO control voltage versus frequency curves.

PLLs are quite convenient for easy selection of increments of frequency spaced at multiples of the phase detection reference frequency. The convenience there is to fit human beans' desire to have decimal values. PLLs themselves will lock just as nicely to non-decimal increments.

The most difficult part about making a PLL at L-band or higher is layout and testing. Already-made "eval boards" have taken care of layout and manufacturers have already tested them to insure that customers can make a product work (and thus induce customers buying a large quantity). Nearly all such eval boards of today use a complex IC SOC which needs a digital data input (usually serial) to set the internal synthesizer. The task of making such a controlling device/circuit/whatever may be as hard or harder than fussing with an L-band controllable-frequency RF source by itself. If one has a microwave source but no instruments or other ways to check it out, the entire task becomes rather moot. :-)

I'm just tossing out some alternate ways on accomplishing a desired task by another. There are many ways to do the task successfully. It is helpful to get detailed suggestions for homebrewers (such as Laura's) and not some general "it won't work and the IC gets hot" non-specific remark. :-)

Hi,

I'm getting rather poor signal reliability using an ordinary
telescopic
whip for r/c purposes. I was thinking about going in for something
tuned,
but a full half-wave dipole for example would be far too big and
cumbersome. Does anyone know how I could go about making up my own
ariel specifically for this frequency? I was thinking maybe a 'rubber
duck' or something similar
that's mostly coiled up? Anyway,
something small and compact. Any suggestions please!

Thanks

After a while of lurking, Ive decided to pipe up with a question.

I am looking to build a tube bc/sw radio that would not look out of place in the 30s or 40s. Homebuilt appearance is desired for what I am wanting to do with it. So that puts the AES kit on it's ear as it uses a mini-tube.

Ive looked on the web for kits and have come up with hardly anything worthwhile. Ebay is no good, homebrew stuff is too expensive and I want the satisfaction of building something of my very own.

A little of my background. I am a ham, no-code tech, and have been since 96. One of my hobbies, what this radio will be for, is reenacting WWII. This is one of my hobbies that I most likely cant afford, but it wouldnt be a fun hobby any other way, would it? I am in the process of restoring an S-20R, waiting on fresh tubes right now.

I work assembling cellemetery equipment, so I have a small, but growing, knowledge of electronics and have built a crystal radio, not that a semi-trained monkey could'nt, and have helped with a few other things.

Many thanks in advance,

Jeremy Becnel
KC5TEK

Jeremy,
Aha...found you here too!

Back to elaborating on my other idea....get an old junker homebrew
'radio box' from the 20s-30's and get hold of a chassis with a destroyed
or no case and rebuild the circuit into the old box. Thats kind of
halfway between a kit and a homebrew and can be done very inexpensively.

I disagree with the idea of building a PLL from discrete components.
That's unnecessarily difficult and error-prone. Go to
http://wireless.national.com and spend an hour or two becoming
familiar with their parts and their design and simulation tools.
DigiKey sells the LMX23xx parts (an LMX2326 like the one my project at
http://www.qsl.net/ke5fx/synth.html uses is a reasonable choice for
1-3 GHz work), and a suitable VCO might be a Mini-Circuits ROS-1000PV
(http://www.minicircuits.com/cgi-bin/spec?cat=vco&model=ROS-1000PV&pix=ck605.gif&bv=4).
Use a narrow loop filter -- 1 kHz or less -- and you'll have no
trouble achieving the VCO's 10 kHz noise spec of -104 dBc/Hz.

A couple of hours spent at the National WEBench page *will* save you
many hours at the workbench, and you'll come away with knowledge that
will enable you to design a synthesizer with reasonable performance
for just about any common UHF/microwave application. Trust me --
don't waste your time messing with TV tuner prescalers, homebrew VCOs,
7490s and 4046s. I'd sooner use 12BA6s at this point. :)

A couple things: I once had the radio-to-antenna wire break
inside a R/C transmitter. The result was very short range. Is
what you're seeing recent or did it always happen?

Another trick: The antenna is 1/2 of a dipole. You can add
a dangling ground wire to act as the other half.

I don't know of any non-volatile PLL chips, although it would be nice
if they did exist. But it's a bit irrational (I dare say) to be
afraid of PIC/Atmel-style microcontrollers. They cost next to
nothing, can still be obtained in low-pin-count DIP packages, can be
(re)programmed from your PC with $1.98 worth of hardware, and they
have tons of online support resources and example applications to rely
on. They're a lot like the all-in-one PLL chips sold by Analog and
National -- once you bite the bullet and spend a weekend climbing the
learning curve, you'll agree that it'd be ridiculous to go any other
way for most applications.

> So 1000/10 is a lot of multiplication and
>possible spurs.

You're absolutely right -- long multiplication chains are yet another
recipe for frustration. You can literally solve this problem in an
afternoon if you're willing to come up to speed on the available
technology. One 16-pin microcontroller (I think some of the PICs are
even available in 8-pin DIPs), one PLL chip, one VCO, and you're done.

Get a copy of "Radio for Millions." AES has reprinted copies and Ebay
has originals sometimes. It has a bunch of projects from Popular Science
of the war years, when parts were scarce. Some of the articles have detailed
drawings on making cases from wood or sheetmetal scraps. You can put
together a pretty cool radio for a few bucks. My favorite is a two-tube
superhet. You'll have to do some parts scrounging, but nothing is
so critical that you couldn't do a bunch of subs. You can get dead AA5s
at flea markets and garage sales for free and most of the parts you need
will be in them.

Have fun.

Steve

Can someone tell me how an SWR meter works? I'm looking at the SWR meter project described at:
http://www.arrl.org/members-only/tis/info/pdf/9702033.pdf

I know that an SWR meter works by detecting the differences between the forward and reflected powers. In this particular circuit, the forward and reflected powers are sent into an LM3914 chip. I am familiar with the functions of the 3914 chip. The forward power becomes a forward voltage that is used as the high reference voltage level. The reflected power becomes a reflected voltage that becomes the signal that the LM3914 chip tests.

The forward power and the reflected power look like they are fed into virtually IDENTICAL circuits. (Notice how both the forward and reflected sides are fed into a Ge diode. And the positive side faces the transmission line for both.) I know that there are couplers in this circuit, but I am having difficulty understanding what's going on. How does this circuit ensure that one part of the circuit responds only to the forward power and that the other part of the circuit only responds to the reflected power?

Hi!

Anyone who have any data on the first mixer in Drake R7/TR7. The picture
of it in the R7-manual says

VARI-L CO.
SM-759

In the list of components Drake calls it CM-1HF double balanced mixer.

Anyone who have information, a data sheet, or any idea on the data of this
mixer?

Jason

I find it easiest to think in terms of the forward and reflected waves on the three transmission lines. On the main line we have the a forward wave and a reverse wave which are the fundamental quantities we are trying to measure. (although eventually they are combined and presented as SWR) Each has a voltage component and a current component linked by the characteristic impedance of the line.

The two coupled lines have forward and reflected waves induced in them by the proximity coupling to the main line. Their amplitudes are proportional to the amplitudes of the waves on the main line. (The ration of current to voltage on the coupled lines is determined by the characteristic impedance of the coupled lines which will be higher than the main line because of the smaller conducter dimensions)

An important peculiarity is that the coupled wave proportional to the main forward wave travels in the reverse direction to the main forward wave and like wise for the coupled reverse wave which travels in the opposite direction to the main reverse wave.

If opposite ends of the two coupled lines are terminated by resistors which can be adjusted to the coupled line characteristic impedance and a voltage detector is placed on the other the reverse wave can be nulled out on one and the voltage from the detector is proportional to the forward wave amplitude (on the main line). On the other the forward wave is nulled out and the detector output is proportional to the mainline reverse wave.

Hope this helps

It's always been a problem. And you really *don't* want a large model
helicopter spinning out of the sky. I've been told I ought to be able
to fly it for as far as I can see it so that's what I'm aiming for for
safety's sake.

>Another trick: The antenna is 1/2 of a dipole. You can add

Thanks, but still too long. I'm hoping to be able to rely on a coiled
design of some sort and just carefully match impedences. If anyone's
got any formula for arriving at just such a suitable ariel, I'd be
very keen to hear.

I checked my R7 manual and it looks like the mixer is a pin-for-pin match with MiniCircuits plug-in balanced mixers. (Others also use the same pinout.)

Drake seems to have reversed some of the nominal connections, but this is not a problem as these devices are symetrical.

The injection level is 1 volt RMS according to my R7 manual. That corresponds to 20 mW, or +13 dBm. So, a Level 13 mixer looks like a good match. These can be found at http://www.minicircuits.com/dg03-102.pdf

Look up the manual for the heathkit antenna noise bridge.

IIRC a schematic isnt quite enough to go by, the physical layout is somewhat critical.

This one is very easy to understand. The two pickups on the stripline
are arranged in opposite directions. Each pickup has a 50 ohm load on
one end and a diode on the other end. The 50 ohm load dissipates the
coupled wave in one direction and the diode rectifies the coupled wave
in the other direction. Each pickup is designed to respond to a wave
traveling in only one direction. The forward sampled voltage is rectified
and the reflected sampled voltage is rectified before being presented to
the LM3914 chip, i.e. the LM3914 is working only with DC values.

I thiink the question is why don't the sensors pick up both, and how do the sensors know which way the wave is travelling?

Maybe Jim Thompson over in sci.electronics.design has a few?
Actually, I don't know if designed the MC1648, but he did design
the MC4044 phase detector.

The device is at least 30 years old. The only good reason for
using it now would be to repair something that uses it.

There really isn't much to it. The actual oscillator is relatively
simple, and could be done with discrete components. Most of the
circuitry is buffers or maybe even level shifters. Unlike some ICs
that actually were VCOs (and used RC networks for timing), it's
only an oscillator; you will need an external varicap to make it
a VCO.

I have no idea where to find them nowadays. Even when they were prime,
and showing up in ham magazine articles, I wouldn't say they were
commonly available from places that dealt with hobbyists. I had one,
once, and I got it from a commercial distributor (and promptly killed
it by putting a wrong load on it; the oscillator still worked, the
buffer was gone).

I thought I explained that. With one pickup, the forward wave sees a ~50
ohm resistor and is dissipated while the reflected wave sees a diode and
is rectified, filtered, and routed to the LM3914. With the other pickup,
the forward wave sees a diode and is rectified, filtered, and routed to
the LM3914 while the reflected wave sees a ~50 ohm resistor and is dissipated.

There is a replacement for it, with a similar number. I think I found it at
On Semiconductor (was Motorola).

Probably just as hard to get hold of, though.

I think a good first choice would be a single-tube regen using a dual triode tube. My 7-yr-old daughter and I built one using a 6C8-G tube (tube c. 1936). This particular tube looks great (octal, ST "pear-shaped" envelope) and is easy on heater current (300 mA). We ran the heater off of 4 C batteries (D's will give twice the lifetime, but even the C's lasted many months), and the B+ came from 3 9-V batteries. You could use a "battery" tube like the 1G6 for even lower filament battery requirements, but they don't glow as nicely!

Here's a typical dual-triode regen schematic:
http://www.qsl.net/wd4nka/IMAGES/2-TUBE~2.JPG

You don't need 90-150V for such a rig. Many were run off of 22.5-45V.

You could also add a power output stage to drive a speaker. A good match to the 6C8-G would be the 6G6-G. You could even drive this combination quite respectably using batteries, using bigger heater batteries and more 9-V batteries for higher B+ (probably 90V minimum), or you could build an AC power supply using e.g. back-to-back filament transformers.

Now let me give my standard pitch for the glowbugs email reflector, where the focus is on homebrewing and operating tube ham gear. The group is quite friendly and will definitely help you with your project. Here's the list info from the radio groups FAQ:

For homebuilding transmitters and receivers using tube technology, there is the Glowbugs e-list; send an email to:

Hi,

I recently bought a second hand 1kW solid state amp. The output filters are damaged, the transistors are still ok. First, the idea was to repair the filter, but after inspection, it seemed that it might be better to replace the entire filter-board. It consists of 6 low pass filters , each switched by relays. Any ideas where i can find these filters (rated at 1kW) ?

Best regards,

Ludo

Hi Cecil, Merry Christmas!

Here's some things on couplers other than microstrip/
stripline octave-band devices, general information on them:

The "Bruene Discriminator" (or "Detector") may have started
the forward-reverse reading transmission line detectors way
back in the early 1950s as part of the Collins Radio
"Autotune" system. That is an RF current-sensing transformer

plus coupled RF line voltage double detector arrangement. There's a good write-up on it, along with current and voltage phase relationship diagrams in TM 11-806, the technical manual for the T-195 transmitter in the AN/GRC-19 military HF radio. The whole T-195 TM is 33 MB in size, available at:

http://www.kg7bz.com/manuals.html

The same TM also describes the final amplifier's automatic tuning system in both text and diagrams...in addition to the separate antenna matching tuning section.

For a good explanation of various transformers arranged as directional couplers, hybrids, and impedance changers:

http://www.mellis.net [click on Tutorials button]

Four HTML tutorials include diagrams with current/voltage relationships shown for better description. Those apply to HF all the way down to audio. There's several other things on Ellis' site which might be interesting to homebrewers.

Not being particularly bright, I played dumb, typed
"mc1648" in to Google and found two suppliers in under
a minute.

You'll want to be sitting down when you see what they
want for them. This reflects the price for a part
that has been obsolete for eons and whose supply is
starting to dry up. Any project that specifies this
part should be retired.

No you didn't!

You just explained what it does, not how or why it senses the direction of
the waves.

Sigh!

How do the couplers work?

The coupler consists of a piece of transmission line with the outer shield removed running from the input jack to the output jack with some form of conductor coupled closely to the transmission line to act as a pickup. The pickup device is either a toroid with several turns of wire around it slid over the transmission line, or, a piece of wire -- usually heavy gauge -- running parallel to the transmission line inside the meter.

As the RF from the transmitter travels along the transmission line to the antenna, an magnetic field is set up around the transmission line -- remember, RF is AC and alternating current passing through a conductor causes a magnetic field to form around the conductor.

As the magnetic field rises and collapses, it passes through the pickup device, which is itself a conductor. As a magnetic field cuts through a conductor, it induces an AC current in the conductor -- in this case, the pickup device.

A diode runs from each end of the device -- this diode rectifies the AC into DC and connects the DC current to a measuring circuit.

Power running from the transmitter to the antenna causes current to flow in one direction, power running from the antenna to the transmitter causes current to flow in the other direction. The diodes pick up the voltage in the two directions and pass that current to the measuring circuit where you select whether to measure forward power or reflected power.

Useful websites:

http://www.lindsaybks.com/bks3/34sw/index.html and
http://www.lindsaybks.com/bks2/joneshb/index.html have collections of
construction articles.

www.angela.com and www.fairradio.com are sources of tubes and sockets.

www.oselectronics has coil forms and variable capacitors.

I believe I would begin with a list of inexpensively available tubes and
look for suitable circuits to use them in.

Have fun!

I just looked this afternoon. $6.95 on their listing of linear ICs.
New catalog on-line, too.

For a datasheet:

http://wwww.ges.cz/sheet/m/

While that is a Czechoslovakian site, it belongs to an
electronics parts distributor and has a number of
datasheets for various ICs in-production, second-sourced,
or perhaps cancelled recently. [replace the "m" in slant
bars with another letter for other part numbers] The
MC1648 datasheet is dated 1997 but Motorola dropped
most of their old linear ICs as well as "legacy" digital IC
glue parts relatively recently.

If you do a Google search of the archive of this group, you'll find some really good explanations about how directional couplers work. I wrote one or two that people years later told me were useful to them, but I know that others may well have explained them better, too. As others in this thread have said, it's that the difference between forward and reverse power is the direction of the current for a given voltage. For each wave, the voltage and current are related by v=Zo*i.

Cheers,
Tom

[snip]

So this must mean that some of the charges/Couloumbs [as represented by
electrons I presume]
are moving in one direction, say to the left, while others, are
simultaneously moving to the right.

Can this true?

I was always taught that like charges attract and unlike charges repel,
positive charges always
tend to move from positive to negative potentials and negative charges
always tend to move
from negative to positive potentials and so *all* of the charges of the
same kind, clearly
these are electrons in RG-58, must all be moving in more or less the same
direction. What?

Heh, heh...

I can just see two electrons passing each other going in opposite
directions, one says to the other,
"Where the heck do you think you are going? The positive direction is down
this way, you'r not
going in the *positive* direction, get with the program!"

I often ask myself, "If I were an electron, which way would I be going now,
and why?"

Thoughts, comments?

Inductors can be made with silver plated wire - Scientific Wire Co
or Hobbycraft. Capacitors from the usual suspects. High voltage
relays are harder to source, can you re-use what you already have
or find them from the original source?

4519. Auto tuner phase detector

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-12-19 14:00:39 UTC
From: jgboyles@aol.com
Message-ID: <20021219090039.27014.00000230@mb-dh.aol.com>
Source record: 39283

Hi,
Anyone got any ideas on a phase detector for a remote automatic antenna tuner I am thinking of building. The tuner portion wil consist of motor driven variable inductor and capacitor in a switchable "L" network. The rf for the tuning process will be supplied from an MFJ-259B back at the operating position.
I measured the output of the mfj into 50 ohms and got 1 volt rms at 20 ma. I am afraid this is not enough for a standard diode phase detector even using germaniums. I suppose I could use zero bias Schottky diodes, but don't have any at the moment and don't know where to get them. Also need ideas on ratio detector so the tuner knows the voltage and current ratio is 50 ohms.
Also the only time rf will be present in the phase detector is during "tune". otherwise the detector circuits will be bypassed. I plan on running a kilowatt from time to time and don't want to fry the detectors.
Thanks for any ideas.

Further to this post
The board artwork is available (Protel Autotrax) at the Website below
The PLL chips are small (SSOP) but can be soldered by hand with care
and the hard work of layout is done
Once you have mastered the PLL design from the National website (you dont
need a lot of math for this), you then have to work through proramming the
chip from a suitable source.
Using a micro is probably the best solution. While this is quite of bit of
work to master, it is becoming easier with all the tools available now and
programming is quite cheap and easy from a PC. Once you have mastered this
and have a working microcontroller system (I would use Atmel - mainly
because I already have a board that works), you have a powerful solution for
all sorts of RF and other control problems and the work will be definitely
worthwhile.

I agree with John Miles - you will spend a lot of time trying to
troubleshoot a discrete design using various legacy chips with no guarantee
of success. You will need a good set of test gear including suitable signal
generators and a spectrum analyser
In the end you will not be able to extend the design for other projects.

Richard

If you read about how DSP works it would scare you (well, it did me) :O) I tried a Rat Shack one a while back but it wasn't that good. It went between the rig and speaker. I believe the DSP units in rigs are in the circuitry and because of that can be more effective.

Clean audio is always nice with some filters giving better results than others. Just this morning I was re-organizing a bit and decided to put a Bencher audio filter between rig and speaker. It worked for SSB and was better on CW, but nothing outstanding. The filtering in my TS-850S does just as well. Think I'll part with the Bencher. This afternoon I'm going to put my Autek QF-1 in and see how that compares. I used to use it with the old TS-820 and it did a pretty good job.

I mean, both work...just that the QF-1 is better.

Good luck with your search...I'll be interested to see what's out there.

I have the mobile model by the same company.

Sounds like your amplifier has seen a high VSWR and smoked some of the
capacitors.

These are high voltage ceramics and are easily replaced.

I do not have a schematic of your amplifier but I imagine the chebychev
filter network is very similar to my amp.

Let me know if I can be of further help.

The waves in water are not the water molecules. The waves in the free electrons in a wire are not the electrons. The waves in both instances are the energy, not the particles.

If I put a steel bar to your head and hit it with a hammer, do you really think a steel molecule has moved from one end of the bar to the other?

If you anchor a rope at one end and then pop the other end, is the wave moving down the rope causing rope molecules to move from one end of the rope to the other?

> I often ask myself, "If I were an electron, which way would I be going now,
> and why?"

Electrons in a wire move in the direction set by the total emf which is either positive, negative, or zero, but they certainly don't move at the speed of light. We are discussing wave energy not physical movement of electrons. Just as water molecules carry wave energy without moving very much, electrons carry wave energy without moving very much.

Which way would you move? Knowing how ornery you are, you would probably choose a fractal pattern of movement. :-)

Unlike obsolete solid state devices, which tend to
disappear, there is a plentiful supply of NOS tubes.

I prefer to use the available supply to maintain tube-
era equipment, like my Collins 51J-4. I'm baffled at
new construction with tubes. Whatever turns your crank,
I suppose; tube construction doesn't turn mine.

[snip]

Heh, heh... Me? Ornery? :-) Hey I never said electrons move at the speed
of light!

You are putting words in my mouth. Where or when did I ever say that?

Heh, heh...

As my favorite President used to say, "There you go again."

Attempting to change the subject to avoid the issue. Well Cec that just
won't work!

As I am sure you know, electrons move at the drift velocity which is
substantially
less than the speed of light.

This is analogous to the speed of the water molecules in a water pipe
[slow], and the
energy transmitted by those water molecules [fast]. The energy always moves
a hell of
a lot faster than the drift velocity of the particles that "carry" it.

The "energy" being transmitted by the slowly moving electrons in a metallic
conductor
often moves at close to the speed of light, but the electrons themselves
often move
at only a few meters per second. [It all depends on the density of the free
electrons.
You have to understand moles, molar measures, Avagodadro's Number and the
metal's density to compute the actual density of free electrons and their
velocity

given the value of the current.] But then Cecil I know that you already knew
all of that, and... BTW...

What the hell does the electron velocity have to do with this discussion anyway?

It was/is the electron's *direction* that we were discussing not their speed!

Jeeesh! ;-)

Happy Holidays,

Hi Guys;
I have for Sale:
1)- 4 Ceramic couplings.
Price is $15.00ppd>>
http://www.myradioroom.com/4couplings.jpg
2)- US Army Audio filters NEW, Marked FL-5C
Price is $13.00ppd>>
http://www.myradioroom.com/armyfilter1.jpg
http://www.myradioroom.com/armyfilter2.jpg
http://www.myradioroom.com/armyfilter3.jpg
3) Johnson LP filter for 72 ohm w/box.
Price is $20.00PPD>>
http://www.myradioroom.com/johnsonlp.jpg
4)- Yaesu 2-meter converter board for FR-101 SW receiver, these are super hard to find.
Price is $50.00ppd>>
http://www.myradioroom.com/fr101-2mtr.jpg
5- Bogen Desk mike, by astatic & looks like Drake model but better, has switchable impedence, excellent!
Price is $50.00 ppd>>
http://www.myradioroom.com/bogen1.jpg
http://www.myradioroom.com/bogen2.jpg
6)- Hallicrafters HA-26 VFO for 6 & 2mtrs for thier AM rigs, in original box w/papers, like new & hard to find.
Price is $60.00ppd>>
http://www.myradioroom.com/hallivfo1.jpg
http://www.myradioroom.com/hallivfo2.jpg
http://www.myradioroom.com/hallivfo3.jpg
7)- Three Hi-Quality VU meters, all Brand new, 2 are simpsons.
Price is $50.00ppd>>
http://www.myradioroom.com/3vumeters.jpg
8)- Johnson Ranger II reliminary assembly instructions, new in original mailer,
Price is $20.00ppd>>

How can you decide direction without also deciding speed?
Going north or south at zero speed is the same thing.

I am not a amateur radio operator but I do have a lot of low power devices that I run off of a box full of wall warts.

Anyway, a 40 buck Radio Shack power supply that runs the CB radio and my SW radio went south on me. I was thinking that what I needed was at least one good well regulated well filtered bench supply that could run any one of my devices on it in a pinch and would have a long service life.

I was thinking of getting a Astron VS-20M linear power supply-variable from 2-15 volts with a continuous rating of 16 amps. I know it would be over-kill as far as my power requirements but that wouldn't be all bad either.

What do you think? Would such a PS work well?
Beowulf

Hey don't you remember your calculus and the theory of limits?

It all depends upon from which speed you approach stationarity.

If you approach zero speed from a positive speed, in the limit you get zero speed.

If you approach zero speed from a negative speed, in the limit you get zilch speed.

North and South have nothing to do with it because its a guided system.

Come guys, it's not what you say it's how you say it...
Your face could stop a clock... We know what that means but it's not nice!
Time stands still when I see you. Not as direct but we get the meaning!

Another axiom: If you can't explain something to others so that most of them can understand you probably don't understand if yourself!

So lets see if I meet line!

Since I've gotten older (62) I don't remember some things as well and to refresh my memory I got a copy of Bruene's 59 QST article and re-read parts Walt Maxwell's book Reflections.

The question was, how does a sensor for an SWR meter work as it seems like the diodes aren't smart enough to know forward from reverse! Walt explains that in the forward wave the voltage and current are in phase. However when a wave is reflected, the current is 180 degrees out of phase, (page 3-6 or 3-7 depending on issue) and that is because the current has changed direction to come back to its source. Bruene goes a little further saying that voltage and current on a line can be considered to have 2 components, a forward and reverse and explains that with phasor diagrams. So remember that current is moving forward to the load and any mismatch causes a reflected current coming back to the source. The returning current is 180 degrees out of phase (as it must be) and is real true power in that it can be used to heat a resistor. Walt points out that some writers have furthered the misunderstanding of reflected power by saying that is not real power because they have incorrectly assumed that the current is 90 degrees out of phase. And if you recall P=ExI for DC and P=ExIx cos. (phase angle), the cosine of 90 is zero but the cos. of 180 is ONE.

OK, now lets put a leg of the transmission line thru a few of turns of wire (transformer) and connect each end to the cathode of a diode, each diode going to a microammeter that is grounded. We also need a dc ground return for the transformer so lets connect a 100 ohm resistor to each end of the transformer.

Now here comes that part that should explain what happens. The forward current will induce a current in the transformer according to the right hand rule and only one of the diodes will conduct giving us a relative indication of the forward current. The other diode can't conduct from the forward current because it's biased off. But as soon as there's reflected current it will turn on, start conducting and send a relative amount of current to the other meter while the other diode is biased off.. I've left out the capacitors and rf chokes for simplification. This is hard to do without a blackboard but lets see if this helps.

Hey Tom:

[snip]
"Tom Bruhns" <k7itm@aol.com> wrote in message
news:3200347.0212191040.43f7509b@posting.google.com...
> Soooo, Pete, do you believe the transmission line is a linear system
[snip]

Yep, the transmission line, the one we are all discussing, is a linear
system.

And furthermore all of the accompanying force fields are considered to be
conservative.

The mathematics is all very clear, at least to me, heh, heh...

Here, I'll recap.
--
The "voltage wave" variables are labeled A and B, the "circuit" variables
are labeled V [Volts] and I [Amps]. Of course one could work with
current wave variables or even normalized dimensionless wave variables,
but it really doesn't matter since, mathematically at least, the wave
variables
are nothing more than simple linear combinations of the electrical
variables.

The "reflected voltage wave" at the plane in question is: B = V - RI
and the "forward voltage wave" at the plane in question is: A = V + RI.

In matrix notation: Waves = [Matrix] x Electricals, where matrix is:

|1 -R |
|1 +R|

The "waves" are simply related by the linear reflection coefficient rho.

rho = B/A = (V - RI)/(V + RI)

The VSWR, and the ISWR since the system is linear, would indicate
the ratio of the largest to the smallest voltage on the media if the media
had any length, but it also holds for an infinitesimal lenght and is defined
in terms of rho as:

VSWR = (1 + |rho|)/(1 - |rho|)

Where V is the voltage across the reference plane, independent of the
path taken in the evaluation of the line integral which defines V, and I is

the current flowing in the positive direction perpendicular to the plane.
R is a function of the reference media and because of linearity this
reference impedance [characteristic impedance] is equal to the
ratio of voltage to current in that media, R=V/I.

The so-called SWR meter is just an analog computer which measures
V and I and then computes B = V - RI to give an indication of reflected
voltage [cfr. Reg Edwards TLI!]. To make the mathematical division
operation simple, most simple VSWR meters then force or assume
a nominal unit value for the forward "wave" i.e. letting, A = 1.0, or else
they utilize a nomographic analog divider [crossed needles indicating
A and B on separate meter needles] thus providing an indication of
VSWR.

And so... in simple terms, a VSWR meter is an analog computer with
analog sensors which measure V and I at a point/plane and then compute
VSWR according to the above mathematics for display.

Such a meter if it DC coupld and is well designed can provide an
appropriate indication over all frequency ranges down to and including
DC, whether or not there is an actual transmission line present, or whether
or not, say in the case of DC there is an actual standing wave present.
--
See, I know all that mathematical stuff!

But wow... all that being said, I understand the mathematics, but I still
don't understand in a physical sense how the sensor detects which
direction a wave is going! What the OP wanted was a simple
physical explanation. How difficult can it be?

A = V + RI goes one way and B = V -RI goes the other, but...

What the heck are A and B? What are they made of? [Both
volts and amps in linear combination.] What do they look like?
[On a scope they would be voltage sine waves or simple DC
values for DC "waves".]

But that's not satisfying enought for me...

You know, I want a physical explanation, not a mathematical one!

What does the forward wave A actually look like and what does
the reflected wave B actually look like, and how can I tell
one is going West when the other is going East? And are the
electrons in A going in the opposite directions to the ones in B?
Or are all the electrons going the same way in I?

Inquiring minds want to know!

Happy Holidays,

--

Source record: 39200

I suspect that most of the devices run off 13.8 or close to it, certainly the CB and if the SW radio was using the same supply, well. More than likely many (but probably not all) of the wall warts are also somewhere between 12 and 15 volts.

Personally, I'd find it real annoying to shut off the radio so I could turn the power supply down to power the drill, or whatever, so I think I would just be inclined to go with a single voltage supply, something like an RS-25, say. Although you can never have enough amps, so think hard about something like an RS-50 ... the price differential isn't all that great.

Now about Astron linear supplies in particular ... plan to reinforce the desk, those things are heavy! BUT, it sure is nice to have that RS-35M sitting in the corner pumping out 13.8 volts, rain or shine, year after year, never asking for attention or making a sound...

If you are in the basement AND have some ventilation, you might consider a car battery and charger. Modern microprocessor controlled chargers are pretty bright about keeping the battery topped up, and you can probably get a pretty hefty battery and a charger for about half the price of the Astron. But you would like a concrete floor in case of a spill and a drafty place where you aren't going to collect hydrogen. Has the added advantage of continuing to operate when a thunderstorm takes out the lights.

..

I've had great luck with my Astron VS-50M. Zero trouble. Would be overkill for you, but it would be there for any future expansion, such as if you ever DO get into ham radio...most HF rigs running 100 Watts need at least a 20 Amp supply....something to think about.

Couldn't I run two or more devices at once so long as they both have
the same voltage requirements? Wouldn't the PS see two devices, one
requiring 3 amps, and one requiring 6 amps, but both requiring 13.8
volts dc as one load of 9 amps at 13.8 volts dc? Or do I
misunderstand?

>Personally, I'd find it real annoying to shut off the radio so I could turn

For the low power devices I'm thinking of making a outlet box and each
outlet with a different voltage from 3-12 volts. Each outlet would be
controlled by a 78xx regulator and I would set the Main PS at at 13.8
volts dc and feed it into the box. Each regulator would give me about
1 amp each. Does this sound like it would work?

Thanks for your response,
Beowulf

Source record: 39206

Hi Keith:
I have been playing with various Commercial Speakers...Motorola, GE, Midland etc and have found that on my TS-570, the Midland Speaker sounds the "best"...for my ears anyway. I believe every person has a different audio curve for his/her ear resulting in hearing the highs or lows at different amplitudes.

I am now trying to find a suitable speaker for the HF rig in the car...the Midland seems to filter out the QRN a bit more than the other units, although ALL are probably designed for audio response of 300 - 3000 Hz and I'm sure the location of the speaker will determine the audio response. I've been using an external GE Speaker in the Left hand corner of my Dash (closer to my ear) and the audio has a tendency to bounce up..off the window giving me reasonable audio level and a different audio response then the speaker ALONE on the bench.

I've used the QF-1 Filter, but believe it is an analog audio filter...did the job but not for this purpose.

The W9GR DSP filter, I used to have, worked really well in the Noise Position, but would be too big for this application..besides, I sold it a while back as my TS-570 has all the DSP I needed.

The DSP concept is interesting, and have been doing LOTS of searching on Internet for DSP chips/kits to buy to play with. Maybe easier to go and buy the ClearSpeech Mobile unit, but then we don't learn anything...HI!
Tnx for the response...will keep looking and adding another project to the existing List!

Whenever the technology jocks in this group go around the mulberry bush, as they
often do, I am reminded of what Humpty said in Alice's Wonderland.

--
"When I use a word", Humpty Dumpty said, in a rather scornful tone,
"it means just what I choose it to mean, neither more nor less."

"The question is", said Alice, "whether you can make words mean so many different things."

"The question is", said Humpty Dumpty, "Who is to be master: - that's all."

--Lewis Carol, "Alice in Wonderland - The Turtle soup"
--

I wonder who is the Master of Reflections? Heh, heh...

The Astrons are very good supplies. I have used them for over 20 years in various applications. The only problem that I have found with them is they can be gliched if the 110 volt AC power goes off andback on very fast, like the lights blinking in a thunder storm. The over voltage protection circuit will activate. You then have to shut it off for a a few seconds , then turn it back on. I have a 50 amp Astron powering several of my ham transceivers at the same time now. It loafs along as about the most I pull is 30 amps at one time.

> one load of 9 amps at 13.8 volts dc?

Yes, exactly. I was assuming that you wanted a variable voltage supply
because you had a variety of different voltage wall warts.

> For the low power devices I'm thinking of making a outlet
> box and each outlet with a different voltage from 3-12
> volts. Each outlet would be controlled by a 78xx regulator
> and I would set the Main PS at at 13.8 volts dc and feed it
> into the box. Each regulator would give me about 1 amp
> each. Does this sound like it would work?

That would make good sense. The only thing I would be a little careful
about is to measure the voltage out of the wall warts with the device turned
on. Most wall warts are unregulated, and a 15 volt wall wart may very well
deliver 8 or 9 volts under load. Since they typically come with the device,
but are often supplied by a third party, it could very well be that 15 volts
could toast the device even though that's what it says it needs on the wall
wart.

The other little gotcha is that sometimes it works the other way. Most "12
volt" devices actually expect 13.8 volts and will often run just fine at 15,
so they will have a 15 volt wall wart. Most often, these devices will run
just fine off 13.8. However, sometimes, especially when they are used to
charge internal batteries, they will actually need the full 15 volts.

I'm considering buying an LC meter, mainly for the inductance measuring capability. I don't need a lab quality bridge, just a simple hand-held device will be ok. Just trying to find out people's experiences with various brands and the pro and con of each.

Thanks for reading the posting and hope you have an enjoyable holiday season.

OK!
I can't believe all the responses to this question! All of this was appreciated.
My original post was for a PLL board which was programmable by parallel data so that the dividers could be hardwired, eliminating the need for any processor circuitry.

There was a firm selling such a board a few years ago. The sold prototype boards for TO-5 RF amplifiers and VCO's. I since lost track of them.

Here is what I have learned:

Don't try to do direct synthesis at 1 GHz too much phase noise.
Multiply from a crystal.
Use a narrow loop filter -- 1 kHz or less -- and you'll have no trouble achieving the VCO's 10 kHz noise spec of -104 dBc/Hz.
Etc.

I have decided to resurrect an old GLB synthesizer board (80's vintage with a Motorola 1414x?? chip) and strip off the on board VCO and substitute a prescaler in its place. An outboard minicircuits VCO will do the heavy hauling. I will have to rejig the dividers to work with the prescaler and external 10 MHz reference. The loop will be another task because I am not sure the GLB has the voltage swing or fioltering required. Of course I will need a active filter to provide low noise VCO supply voltage.

I am building a converter to allow a 0-1 GHz spectrum analyser/tracking generator work up to 2 GHz. A 2 GHz LO would get me to 3 GHz, so I am also looking into making the PLL work with a second VCO for that range.

The Heath impedance bridge goes for about $20 or less on EBay -- it isn't a Genrad or HP, but nicely acurate for the money. Only drawback is that you need a pair of 9 volt batteries.

I am not fond of the little add-on kit sold by Jameco.

I also have that AADE meter; it is a good unit. It operates at approximately 750kHz, so there is enough inductance reactance even with small value inductors to make relatively precise measurements. He also has a good filter design program. Not quite Eagleware, but good bang for the buck.

There is one nice thing about these wall warts, they provide an
isolated power supply to only a single device. This can become
important, if actual load devices are connected together with e.g.
audio cables, since all kind of ground loop problems can occur.

Some devices might have positive grounding, thus a floating power is
nice if you intend to connect devices together.

Also some devices, such as battery charges, may expect a quite high
power supply impedance to limit the charge current.

Some wall warts are actually transformers, feeding AC to the device
and the devices may generate positive and negative voltages
internally.

>bad either.

If you run all devices from the high current power supply, it is a
good idea to install fuses to the individual DC power lines, since the
small power cables might melt, if a large 15-30 A short circuit
current would flow if the load device failed.

The wall warts have quite different output voltages, so if you want to
run different devices simultaneously, you might have a problem. A
better solution would be to have a high power 13.8 V orlarger power
supply and use individual 78xx regulators for each load device. Even
if one load device would be short circuited, only that device is taken
out by the current limitation of the 78xx, 78Lxx etc. regulators.

>
>Jack K8ZOA

Ok, thanks Jack. I have heard about people who have redesigned their TR7's
to get higher IP3. This mod involves changes to the first mixer. I have been
thinking about doing this myself but wanted to know a bit more about the
original circuit.

I got to the same conclusion as you, i.e. that the original is a level-13-
mixer, but was a bit unsure, so better ask :-)

I have a SRA-1H, a level 17 mixer, that might be a good candidate for the
mod. But I need to make a redesign of the LO amplifier also, to reach this
level, +17 dBm. Perhaps I will try to get hold of a SRA-3H instead, it has
a 0.05-200 MHz RF port, SRA-1H has 0.5-200 MHz which may not be good in
an R7.

I see that Minicircuits also have Level 23 and 27 mixers... might perhaps
be something to try... :-)

Ho Ludo,

>Thanks for taking the time to read my post.
>Actually the core material is burned, the capacitors seem to be ok.

SMOKING

I've just checked my 'Metron' amp manual and the part numbers or
description of the filter inductors do not in any way tell you what
brand or type of ferrite core is used.

IMHO Type 43 offers the best overall performance from 160-10m.

However I've just found the business card from my last point of contact
at Datron who it seems are now part of Titan Systems Corp.

You may wish to contact David Bradley who's e-mail is;

dbradley@titan.com

You'll receive my consultancy invoice at the end of the month:-)

Happy Christmas.

Except for the fact that the meters are reversed, and there is
no Reflection Coefficient scale, I believe the Autek Research
WM1 Deluxe Computing SWR/Wattmeter would fit your bill. I have
one and like it, and an added bonus is that it can read Avg Pwr
or PEP:

Hi,

Can anyone point me to any sources of information on design
considerations/construction of the 'rubber duck' type of antenna?

Thanks.

>I'm looking for articles published in QST on solid state amps.

Hi Johan,
I suggest you go to the communication concepts webpage
www.communication-concepts.com
and download the Motorola application notes on solid state Amps. These were written by Granberg (SK). The articles he wrote in QST are based on these application notes.
I just built an amp using 2 of the EB104 type boards (8-MFR 150 FETs) for about 1200 watts pep output. Got all the components for the rf deck from Comm concepts.

> I am looking for a circuit schematic for a simple 6 meter SSB (Upper SB)
> single frequency reciever (reciever only) to monitor 50.125Mhz.

What I did for a long time was simply use a FM-only scanner on
50.125. If the squelch ripped open with sigs and modulation, then
I'd go down to the shack and see "wazz up".

Now-a-days I use a VOX'd FRS walkie-talkie hanging in front of
the speaker in the shack -- with with a scanner or two, and another
FRS W/T monitoring the FRS channel -- sprinkled about the house
and garage.

I don't use an All-Eggs-In-One-Basket rig: I have an IC-551
for Six, IC-251 for 2M, and a TS-520 for HF. So, I can monitor
6M continuously -- without 'upsetting' any other activity. Maybe
that's the 'wrinkle' you're trying to overcome...

LO strength is one factor, cleanliness of the LO signal would need to be considered as well. When the rig first came out, some friends bought them up...only to find the LO signal looking less than desirable. With no antenna (just a dummy load), the ten meter band sounded full of weak signals. Drake promised to address the matter with field updates, then came out with the outboard VFO (someone correct me on that, if I'm wrong). And, don;t forget about proper termination of the IF and LO ports.

>Is this a 160 to 10 meter amp you have made ?
>What filters did you use ?

Right now I have 160m-40m filters. I used the 5-element Chebyshev Low-Pass L in/out. I tapped the inductors and added a bandswitch so I can change bands easily. I also had to make a power splitter and power combiner to combine the 2-600 watt boards to get the 1200 watts.
The power supply was difficult. You need 50v at about 40 amps peak. I scrounged up enough volt-amps worth of tranformers at the right voltage to barely make it.
Also had to build ALC circuits. The amp can be driven to full output with 10 watts drive. 100 watts will seriously overdrive it.
As I stated before, this amp is along the same lines as the ones published in QST.
According to my crude instruments, when driven with 10 watts the amp has 20db power gain. When switching from my 100 watt barefoot rig to the amp I can realize 10-11db gain.

could send you the schematic for NYE VIKING power meter (believe it is
part of a tuner), it uses 5 op-amps (an LM324 and an LM358) - it is
not too expensive to make, don't know about the accuracy, but the

problem is to find a frequency independent probe which works - to many amateur constructions aren't too easy to copy with the promissed performance.

Have two different, the old Radiometer MM1e measures down below 50nH,
and the modern digital type I am not certain how accurate is.

It is easy to misunderstand the value of measuring the coils. Started
using similar homebrew instrument in 1962 instead of GDM, and often
couldn't resonate coils because the total capacitance and stray was
much different from what I thought, so still I use the GDM - have two:
Philips GM3121 and a japanese which is not much reliable but doesn't
black out the TV's in the area. Also use Q-meters, but some coils are
difficult to check, so you must find the inductance before trying to
check it with the Q-meter. Have Heathkit QM-1 and Radiometer QM

Greetings all,

Most PLL circuits i have seen have some sort of Colpitts
oscillator that needs to have a slug inductor retuned depending on the
frequency. Basically adjusting the inductor so the tuning voltage is
within a certain range (so the MHz/Volt is within a certain range
too).

Then there are the No-tune designs like the FRB PLL that uses a
Mini-circuits POS-150. This design works very well with no inductor
tuning needed (the whole VCO is hermetically(?) sealed anyhow), from
86-110 MHz.

Does anyone know what is inside one of these rather expensive
POS-150s? I've heard that they probably use a hyper-abrupt varactor
of some sort. Does anyone have a cheaper VCO circuit that mimicks the
same no-tune performance? With minimum parts count if possible.

Slick

4582. Re: Auto tuner phase detector

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-12-21 03:18:25 UTC

Source record: 39245

There are standard designs of phase/magnitude detectors
in the literature, which are very similar to power meter
designs. They consist of a toroid around the center
conductor of a through-line coax fixture and some
Schottky diodes. They are normally used with a lot
more power than the 259B puts out (namely the
transmitter provides the tune power). I suggest
looking at the manuals for some auto-tuners currently
on the market for specific circuits you can copy.
You will probably find they are all basically the same.

To work at lower power levels, you need to bias
the diodes on, so that they will be more sensitive.
This is a standard technique for diode detectors.
There are excellent application notes by Ray Waugh
on the Agilent Technologies web site that explain
this. You can get zero bias Schottky's from distributors that sell
Agilent components.

4583. Installation in Vehicles... for the bemused.

Date: 2002-12-21 03:52:26 UTC
From: "Paul R. Bennett" <rffox@gru.net>
Message-ID: <3E03E599.4412115C@gru.net>
Source record: 39246

Good day.
Now here is the situation.
My previous vehicle was a '74 Dodge Powerwagon... I bought new.
Obviously lacking in all the mod coms. I had installed lots of radios
in her... up to, and including a Swan 500C.
That was then... This is now...
Most recently I replaced my dear old truck... had to, like it or not.
She went to her rest.
And I have a new vehicle and need to install my radios. But, now I am
dealing with computers and all kinda fancy gizmo's... difficult for
someone whose idea of advanced computing is a slide rule... heheh....
and tubes rule :>
Well, I now have a '95' Ford Escort LX Station Wagon... with airbags...

And I am concerned. I am not putting the Swan 500C in her... but.
My intended installs are:
HF: The Heathkit version of the Yaesu FT-747
VHF: Radio Shack HTX-212
6 Meter, 10 Watt Aziden
And I have been accumulating the appropriate, or so I hope, stuff. Most
recently I had some footage of Belden 9913 delivered... I am planning on
using that for the HF side of things.... Between the beldfoil and the
woven shield...
Now I have absolutely no desire to key down and:
Have the Air Bags explode in my face (Not a good idea)
Have the Brakes Lock(ABS is great... sometimes)
Everything just totally die... when the computer does.
Okay...
Is there a website out there, or a source of information on resources
for installing radios in modern vehicles for us bemused who have been
dwelling in the distant ages of the mobile hamming age. And who still
worship before the "Mighty Vacuum Tube"? :>
A website would be nice
Or pointers....
Whatever...
Thank you kindly for your assistance.

Paul R. Bennett

In article <3E03E599.4412115C@gru.net>, rffox@gru.net says...

> Good day.

Hey, Paul...

<snippety-one>

I ran into the same situation when the 'Blue Beast,' an '86 Ford Bronco II that had served me well for many moons, was put to rest about a year and 1/2 ago, to be replaced by a 2000 Dodge Grand Caravan SE (a retired rental from Hertz).

> And I am concerned. I am not putting the Swan 500C in her... but.
> My intended installs are:
> HF: The Heathkit version of the Yaesu FT-747

> Have the Air Bags explode in my face (Not a good idea)
> Have the Brakes Lock(ABS is great... sometimes)
> Everything just totally die... when the computer does.

I can say, from direct experience, that neither is likely to happen as long as you follow good installation practices. Some suggestions:

--Install a separate secondary battery, and appropriate charging isolator, to run the radio gear. Not only will this provide some degree of protection for both your car and your radios, it will also cut down on alternator whine. I've had excellent results with the isolator made by Hellroaring Technologies (no, that's no joke -- it's their actual name!) at http://www.hellroaring.com

--Ground EVERYTHING! Make sure all your grounds tie back to the chassis of the vehicle, and use good-quality lugs and hardware to do so. Do NOT use glass-mount antennas! Use real Larsen/Radiall NMO-series through-hole mounts.

If you don't want to punch holes in the car's roof, do what I did; Get some 19" rack panels, mount the antennas to them, then mount the panels suspended between the roof cargo rack's cross-beams using Adel clamps. For grounding, bond the panels together with 6-8 gauge stranded copper wire, and tie the lot to any convenient screw that bites into the car body (one of the cargo rack's screws should do it).

--DC Power distribution: Entirely up to you. What I did with the van was to take a fiberglass-filled plastic NEMA enclosure, mount a bunch of aircraft-type circuit breakers in it, and wire it up for DC distribution. Works like a champ, and the breakers can often be found through aircraft scrap dealers.

No one has reported any alternator noise whatsoever on my signals, and the ones I've received have very little (from my vehicle) on them. As you might imagine, a year-2000 vehicle like the Caravan has all kinds of onboard controller computers, and airbags. I've not seen any evidence whatsoever of any RFI.

I will soon be putting up a web page detailing the installation I did on the van. Drop me an E-mail as a reminder, and I'll send you the link for it.

Keep the peace(es).

>So you're also using the filters made by CCI ?
> I used the 5-element Chebyshev
>> Low-Pass L in/out. I tapped the inductors and added a bandswitch so I
>> can change bands easily.

No, homebrew. I used T-200-2 cores and standard value mica capacitors. Got the values out of the ARRL Handbook. The 160-40 filter uses three tapped inductors and six caps plus a bandswitch. I used the T-200 because thats what I had on hand. I terminated the filters with a 50 ohm resistor and swept them with an MFJ 259b to check the response and input impedance.
The only things I got from CCI was 2 circuit boards and the components to populate them. I got 4 MRF150s from CCI and I got the other 4 off a surplus MRI circuit board I got at Dayton for $35. This board had 10 MRF150s on it! I estimate I spent $250 US dollars on the whole amp, including power supply.

>what is the IMD performance on SSB?

Good!
Well, actually I haven't checked it with a spectrum analyzer. I have a homebrew analyzer that I need to get out of mothballs. I was pretty careful with the filter design, I swept them with an MFJ analyzer and they were up to FCC requirements. I didn't record the data, so I can't be more specific. Also I was careful setting the bias on the 8 mosfets so hope I am ok. On the air reports have been good, signal is clean, and is a real improvment over 100 watts.

>They are normally used with a lot
>more power than the 259B puts out

Hi Rick,
The low power design constraint I have imposed seems to be the problem. I want to use the MFJ as an rf source because I currently use it when I adjust my manual tuner. Works great in this application, tune for 50 ohm match on the MFJ, switch to rig, start talking.
I have aquired some Schottky diodes. Over the Holidays I have some time off so will experiment.
>To work at lower power levels, you need to bias
>the diodes on, so that they will be more sensitive.

>To work at lower power levels, you need to bias
>the diodes on, so that they will be more sensitive.

I briefly tried this with germanium diodes, but the results were not what I wanted. I assume my bias design needs tweeking.
>There are excellent application notes by Ray Waugh
>on the Agilent Technologies web site that explain
>this. You can get zero bias Schottky's from distributors that sell
>Agilent components.

Thanks, I will have a look.

Source record: 39153

There is certainly nothing wrong with using a separate battery for the radios, but from my experience it is not necessary to eliminate alternator whine or other problems. It's primary advantage is that if you run down your "radio" battery you can still start the vehicle. My only problem with alternator whine was caused by multiple grounds on a 2M rig that had a poor internal grounding system. It was fixed by providing a good direct ground to the case rather than depending on the ground lead provided at the power connector. With a 100 watt HF rig and a 50 watt 2M rig I have not experienced any problems with air bags or other electronics in the vehicle. I would recommend that you avoid bundling the coax cables along with the harnesses to the air bag and other vehicle controllers.

4591. Palomar Loop Ant. ??

I just got a Palomar Loop Amplifier and Palomar Loop Antenna for 160/80 meters. I'd like to wind antennas for BCB, VLF, and maybe other bands. I wonder if anyone has wound any loopsticks for this box with any success. Looks like there's a 2N2222, and 2 MPF 102 in the amp. Any help with a schematic or antenna info appreciated.
tnx

FCC rqmts are... -30dBc?

a strong signal is great...but a clean signal 20kc or even 50kc away from the carrier is even more remarkable.

Oh dear! Is it still more of such nonsense about using an amplifier?
Again, you don't need an amplifier if you use a coupling loop with
area of 1/100 of the frame antenna and connect this to 50 or 75 ohm
cable.

Tested such antennas on 136kHz as well as 80 and 160m, somebody
recommended BFT66 or BFR91 low noise amplifier, but background noise
peaks up when antenna is tuned, and this applies to frequencies up to
4MHz, maybe an amplifier will improve receiption on higher frequencies

I did a lot of work constructing different amplifiers on different
loop antennas, only to experience that it was only waste of time, and
no god idea to use high impedance connection to the loop.

My 80m loop didn't have much bandwidth, but without remote tuning it
proved very useful for most part of the 3.5-3.8MHz band (it was tuned
to 3550kHz for the CW segment). It was very useful to avoid electric
noise from the open supply wires, but this is now history and no
problem to use the trap dipole for listening.

Have not tried remote tuning for HF, only for 136kHz band, and it is
over 25dB attenuation when my antenna is tuned to 139 instead of
136kHz, the Q-value is 150.

Thanks All
There were several responses and all helpful.
Tomorrow I will be doing some cable pulling straight to the battery... both leads fused. I have gotten some Belden 9913 for HF.
A bit of an overdo on the shielding I admit.
But still... thanks all.
I admit to having a devil of a time trying to figure how to route the cable, until I found that feed through.
Now all I have to do is figure how to actually mount the rigs...
Thanks again.

If it is "harsh" is something being overdriven?
Alternatively if the audio has too much treble, try adjusting the relevant carrier oscillator frequency. This will probably be a crystal oscillator with a trimmer capacitor to vary the frequency slightly. If the crystal filter passband is not correct relative to the oscillator, you will get an odd audio response.

Richard

Another handy one is the MFJ-259/269 antenna analyzers. You
can measure inductance at the frequency you are using the device
at (or capacitance).

If you have a signal generator you can use that to measure the resonant
frequency with a known capacitor.

Source record: 39163

Ron:

I don't have a design to show you, but I'd like to note that something that works is easy to cobble together. I made a set years ago out of plexiglas, and I've seen comparable sets made with PC board. Just picture two paddles (strips of plexiglas or PC board) mounted above an ordinary wood board, with an ordinary bolt or screw in between them as a ground contact. The spring action isn't as good as you'll find with a Bencher or other commercial model, but it's not bad. I used my plexiglas set for several years before splurging on a (used) Bencher.

Note that you'll need two paddles for iambic operation. You can't do it with a single paddle.

<snip>

Be EXTREMELY careful drilling through the firewall!!!

Check your site for the proposed hole front and back VERY
carefully!

Slip an aluminum spacer or similar sleeve over the drill bit to
limit its penetration to, say, a quarter-inch!

Stick a thick piece of cardboard on the engine compartment side
where you expect to come through!

Line the edge of the finished hole with either a grommet or a strip
of that flexible nylon stuff with the fingers on the backside. You can
find the latter in the Electrical section of marine supply places.

I cannot emphasize the caution points about drilling through the
firewall strongly enough! I got reckless because I was in a hurry, and
ended up drilling through the feed hoses for my heater core. $296 later,
it was fixed -- barely in time for me to leave for my annual scrounge
trip.

If rig mounting is an issue, I'm a reseller for the entire line of
professional radio and accessory mounting systems from SMC. In fact, I'm
using one of their big mounts up front in the van. Would you like me to
send you a digital snapshot?

Good luck.

Hello,

I am looking for the relay that switch TX/RX into the FT902DM. Where can I buy one ?

Thanks for your help

Source record: 39169

When I was building my 2N2/40, from time to time I came across the need to validate an inductor or capacitor and I used an even cruder version of Leon's trick.

I would put a resistor in series with the component under test, of about the same reactance I expected for the component. I then put the pair across the output of my Fireball 40 transmitter, and measured the RF voltage across each component. This told me the reactance of the part and hence the inductance or capacitance. (If you're not familiar with the FB 40 it's an extremely simple 40 milliwatt transmitter from NJQRP. A Pixie II or even just one of those oscillator cans would work just as well.)

The only special tool this took was an RF probe, which everyone needs to build as a first project anyway.

4607. FS Meguro MSW-721E IF Sweeper

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-12-22 21:01:47 UTC
From: Joe Leikhim <jleikhim@nettally.com>
Message-ID: <3E06283B.1A88D64A@nettally.com>
Source record: 39170

I have for sale a Meguro MSW-721E AM-FM IF SweepScope. This is a solid state, Japanese made instrument for sweeping/tuning 455 KHz and 10.7 MHz IF's of broadcast receivers. It has two frequency bands and fixed crystal markers. The unit is in excellent condition and works well. It has variable center frequency and bandwidth for each band so you can also interpolate different IF bandwidths using the fixed markers and scope graticule. Simply inject the calibrated output into the IF circuit you are testing and attach a probe to the detector or limiter of the circuit you are sweeping. You will need a simple external diode RF probe if you are sweeping passive devices out of circuit. With a mixer and external LO, you can sweep through the RF stages as well.

The construction is first class, the scope unit is superior.
$325 shipped/insured in US.

E-mail directly to me if interested.

Grins...
I am not gonna do the firewall drill thing... Already had the hood up...
My old truck had enough room so as I could sit on the fender and rest my my feet on the frame....
Not these new vehicles.
Today I "Very Carefully" slid a knife blade through the wiring grommet that passes between the passenger compartment and the engine compartment.
And then fed the cables through.
Ran them to the battery... and... very carefully... cable tied them to the main wiring harness. I made sure the hot and ground leads were both kept separate and clear of the vehicle chassis.
I ran them both to the battery and then discovered I did not have the nuts required to tie them to the battery connections... very carefully cable tied them off.
Both hot and ground leads are fused.
And thanks much for your input... Even before I read it... I carefully inspected the feedthrough site... and Paranoia had its merry way...
Now there is one... little problem I would appreciate some input with....
Room...
For Radios...
So... what does SMC have to somehow squeeze an HTX-212, and an equal sized Azden 6M and a heath equiv of the Yaesu FT-747 in the minimal room available between the shift stick and the radios?
Paul

Hello All!

A question for ya'll to give to give two cents worth of your valued opinion. I have some sealed lead acid batteries(commonly known as gelcells) and looking for some advice on charging.
Looking around I find that most of the chargers out there are mode chargers. Some go by current or by voltage. On the common voltage chargers, they say that during the "absortion mode" the charger limits the charging current to say, around 500mAh or so, and raises the battery voltage to somewhere around 14.4V. Then when the battery is drawing around 30mAh, the charger lowers the voltage to somwhere around 13.4 - 13.8V as in the "float charge" mode.

My question is this, why does the battery's voltage get raised to 14.4V during the "bulk charge or absortion charge" mode? Would it make any difference if I were just attach a charger with the voltage set to somewhere around 13.5V with limited current of, say, 500mAh?

I await anyones' and everyones' informative response.

Appreciatively,
~Benjamin

Specs from Meguro website. Apparently they still offer this unit.

MSW-721E AM-FM RADIO IF SWEEPSCOPE
ï¿½ For testing the I-F cicuits in the AM and FM radio receivers

Sweep Frequency Range: A : 400 to 500kHz, B : 9.5 to 11.5MHz

Sweep Width: A : 0 to ï¿½50kHz, B : 0 to ï¿½1MHz

Output Level (50 Ohm load): 10dB ï¿½6

Marker Frequency:
A : 445 / 450 / 455 /460 and 465kHz
B : 10.55 / 10.625 / 10.7 / 10.775 / 10.85MHz
simultaneous display of 5 markers
Minimum Interval: A : 0.1kHz, B : 1kHz

CRT: 5-inch, electromagnetic deflecotion
Vertical Sensitivity: 1mV / DIV
Vertical Response: DC to 10kHz, -3dB

Dimensions & Weight: Approx. 190Wï¿½275Hï¿½340Dmm ï¿½ 5kg

I have a "Snapit Correct Circuit Tester" (probably purchased from Radio Shack) which plugs into a 120-volt AC U-ground outlet and reports, via three LED's, the status of the outlet's wiring as per the following chart:

0 G 0 Open Ground where O means LED is off
0 0 G Open Neutral G means LED is Green
0 0 0 Open Hot R means LED is Red
R O G Hot/Ground reversed
R G O Hot/Neutral reversed
O G G Correct

QUESTION: WHAT IS THE CIRCUIT INSIDE THIS NIFTY LITTLE TESTER?

Source record: 39180

It would never get fully charged at 13.4 volts. The float voltage
(13.4) can be left on indefinitely
after fully charging. Lead acid batteries like a float voltage. But
they must first be charged at a
higher voltage or they will become sulfated.

The charge current is typically limited to 20 to 25% of the capacity
of the battery to avoid over
stressing the plates. Once the voltage on the battery comes up near
the charge voltage then the
charge current tapers off. Monitoring the charge current at a fixed
charge voltage gives an
indication of the amount of charge the battery has taken on. Then
switching to the float mode
maintains the charge. Maintaining is done to compensate for leakage
that commonly occurs in
batteries.

If you were to leave the higher charge voltage on the battery for long
periods the battery would
be damaged.

Using a charger with too low a charge voltage will never fully charge
the battery and the plates
will sulfate and reduce the life of the battery.

Be sure that the battery is really a gel cell rather than a sealed
lead acid battery. There is a
difference in charge and float voltages.

"CW"
> A bit slow. I think.

Jacques is in the right ballpark.

Of course the average velocity for an electron depends on the current and wire gauge (in other words, current density). I did the math once for a 1 amp current in a 14-ga copper wire and it worked out to something similar to Jacques' number, but I don't recall the exact answer. But it was very slow.

For those NG lurkers that may wonder why the light comes on so quickly when the light switch is thrown - while the electrons might take several minutes...

They need to keep in mind that voltage is analogous to water pressure.

Start a distant water pump and the water at the near end (far, far away from the pump) will start to flow almost immediately (assuming that the pipe is already full of water in the same way that a wire is already full of free electrons). But the particular water that was at the pump when it started pumping (perhaps marked with dye) might not arrive at the other end for many hours.

The pressure wave (voltage) moves very quickly. The actual water flow (electrons) depends on the flow rate (current).

That approximates the best regime for SLA's.

It won't go anywhere near full charge at a float that low. We float
them at 13.8 or 13.85 and probably are getting 90% or better. For
full charge, do as the units described in your first para.

For a good description of what is IMHO the best regime, look up the
data sheet on the Unitrode (now in TI) UC3906. Simple, effective.

Wrong newsgroup. You'd probably be better off asking this in
sci.electronics.repair.

rec.radio.amateur.homebrew is for discussions involving the design
and construction of amateur radio equipment, not consumer stereo
receivers.

The Phillips TDA1591 and others of its ilk are being used nowadays. They don't need the free-run frequency of the VCO to be adjusted. Instead, they use a variation of a VCXO, with a 456kHz resonator that is divided down to 19kHz. I used this device in a redesign of my McIntosh MR78's decoder. Separation is 55db over the audio range. The best I've been able to get with an LM4500 has been 42dB.

From: Kent Haase <ijeh99@mb.sympatico.ca>
Message-ID: <67IN9.6599$7_.27697@news1.mts.net>
Source record: 39186

I've got a Kenwood 2m & 70cm HT that I wish to power from the cigarette lighter socket in a vehicle. Kenwood makes a "filtered" plug and cord assembly (probably $$), but I've got several unneeded assemblies for charging a cellphone, and I'd like to adapt one of them by replacing the charger circuitry with a filter.

What approach should I use to construct such a filter? Lowpass PI filter? What -3dB frequency? Should I filter both sides of the 12V? Do I even really need one?

Any comments appreciated.
Kent VE4KEH

4624. Re: What's inside an AC circuit tester?

Are you sure that these are LED's.

In the testers I've seen these lamps are neon bulbs with a suitable
current limiting resistor (typically around 47k)

If you number your columns 1,2 and 3 from left to right
Lamp 1 is between Neutral and Ground
Lamp 2 is between Hot and Neutral
Lamp 3 is between Hot and Ground

I guess LED's could replace the Neons but they would probably need
reverse voltage protection diodes across them and higher value limiting
resistors. It also seem likely that lamps 1,2 and 3 would light if the
neutral was open when you used LEDs. This does not occur with neons due
to the need to exceed the 'striking voltage'.

You need to make sure the HT will take the voltage the car puts out. YOu
should not need any filter. If you do , it will probaly just take a coil in
series with the hot wire and then a big capacitor to ground.

4626. Gouriet-Clapp osc

Newsgroup: rec.radio.amateur.homebrew

My Eico 722 VFO uses a Gouriet-Clapp circuit. To turn on the osc tube (6au6) for XMT, the cathode is grounded thru a slide switch.

I've considered a more electronic means of switching...such as using a fet switch (capable of enduring the cathode current).

Any suggestions would be helpful.

4627. Would anyone know how to 'eliminate' the hummmm I have in my power supply?

Hello all,

Merry Christmas and a Happy New Year!

I always dabble in making LPFM transmitters, using my LM317T adjustable power supply.

The power supply has been working great over the years, but there has always been a noticeable 'humm' coming from my receivers end.

Would anyone know how to eliminate this humm I have from the power supply.

Sincerely, Patrick

Try placing a 100 to 1000 uF and a 0.1 uF capacitor directly across the output
of the power supply as near to the regulator IC as possible. Note polarity on
the electrolytic type and voltage rating (should be at least 1.5 to 2 times
the highest output voltage).

Is it possible that the magnetic field from the transformer in the power supply is coupling energy into the receiver? If so, move them a few feet apart.

Something I would check is, how much unregulated input voltage is going
to the LM317 and how much output voltage is it set for ?

It is possible that the input voltage from the AC rectifier is low enough
that when the low voltage part of the input AC ripple hits, it is below the
requirement for the LM317 and that would allow the ripple to go through the
regulator and show up on the "regulated" DC output voltage.

That low voltage point in the unregulated DC voltage ripple won't show up
on meters, although an Oscilloscope would see it...

Since this has shown up in more than one of your Transmitters, probably
pulling different DC currents, I would suspect the unregulated DC voltage is
something like 2 volts above the required output voltage, at least when the
power supply is under load.

Personally, I like to see 3 or 4 volts above the output voltage, although
that voltage drop in the regulator winds up as heat when you are pulling
current.

Another thing that might help is to increase the size of the filter
capacitor right after the rectifiers. This results in a larger initial
current surge when the power supply is turned on, but it also provides a
'stiffer' DC voltage to the input of the LM317 voltage regulator.

>
> Any one else have any comments?

Please read all my comments because there is
a few things that i need to point out.

You use different charging methods for the
type of service you are using a the battery for.

If you are using it for fork lift, motive power,
or other full charge/ full discharge application.

You want to bring it to full charge as quick as possible.
set current limit to c/10 or even c/5
So you set the float voltage to ~15V and when the
current drops off bellow c/100 then you have a full charged battery
that's ready to go back into the device it's running.
If you leave them hooked to the unit at 15V they will
broil dry after a while.(ie) destroy the batteries.

If it's a standby application where it's hooked up all the time.
Set charge current limit to c/20
You set the float to around 13.5 to 13.8 and hold it there.
That will keep the batteries at 100% charge and won't over charge them.
But it will take a long time for them to reach full charge.~2days or so....

And the charging rate is based upon the size of the battery.
C/20 means that it's charged at one twentieth of it's rated AH.

There is some batteries called gel cells that you can only charge
so fast because if you charge them too fast, bubbles will form in the electrolyte.
And the damage is usually irreversible.
The charging rate for them is usually limited to C/20 or even less......
If it's a 10AH battery, you can only charge it at 0.5A max.

> >I have some sealed lead acid batteries(commonly known as
> gelcells)
> > and looking for some advice on charging.

That is the main point that the correction needs made.
That common knowledge is INCORRECT KNOWLEDGE

Most sealed lead acid batteries are not gel cells.
They ARE most likely, "Absorbed glass mate."/"Starved electrolyte."

Gel cells are a decent bit more expensive and if a sealed lead
acid battery is a gel cell.... It will proudly proclaim it on the side.

If it doesn't specifically say "GEL CELL" ......
Or "GELLED ELECTROLYTE"
Or "GELLED BATTERY"
Then it isn't a gel cell.

The "Sealed battery is gel cell" myth is one common myth
that you need to realize is false.

I would say that 90 to 95+% of sealed batteries are NOT gel cells.

Most sealed batteries will handle the usage that a normal flooded
cell will handle.

There is one exception.....
You have to avoid applying overly high charging voltages to them.
Because they are, by their very nature.... sealed.....
So once you broil the electrolyte away.... you can't put it back.

> > Looking around I find that most of the chargers out there are mode
> > chargers. Some go by current or by voltage.

Ones that go by current are strictly for cyclic use.
When you charge at c/10.
You hook it up and 10 hours latter, you disconnect it.
Or the timer in the charger shuts it off.

>>On the common voltage chargers,
> > they say that during the "absortion mode" the charger limits the charging

> > charger lowers the voltage to somwhere around 13.4 - 13.8V as in the
> "float
> > charge" mode.

That is the best type for any application.

It charges them close to 15V to get them close
to full charge as quick as possible, then it switches to
13.8 V to keep it at full charge without broiling the battery dry.
That way.... if you forget and leave the battery on the charger
for a day or two....
When you see that it's still on, you won't find a FRIED battery.
You will find a nice fully charge one.

<< The power supply has been working great over the years, but there has always been a noticeable 'humm' coming from my receivers end. >>

Patrick-

This reminds me of a hum problem with direct-conversion QRP Ham Rigs, such as the Heath HW-7. In those cases, it isn't necessarily the power supply causing the hum.

For some reason the local oscillator becomes modulated by 60 Hz. It may be that the shielding is inadequate, or that the oscillator signal gets coupled through the power supply to the 60 Hz side. I've never seen a good explanation, but have read of many others having the same problem as I've had.

My best results in attempting to reduce the hum, were obtained by running both power leads together through a large toroid ferrite core. I looped them through the core several times to notice a reduction in the hum, but never was able to completely eliminate it.

The key to demistifying SWR couplers is to realize that
"forward" and "reverse" voltages are defined basically
as the sum and difference (respectively) of the voltage
and current. The coupled line (much shorter than a
wavelength) is really a lumped component having both
capacitive and inductive coupling, which basically detects
voltage and current respectively. The diode voltages are
the sum or difference of voltage and current. You could
replace the coupled line with a coupling capacitor and a
coupling coil. It's cheaper to build the assembly as a
short section of coupled transmission line.

There may be a few millivolts of ripple from a properly-designed LM317 regulator. The ripple attenuation depends on the output voltage, and can vary between 60 to 80 dB. If the output voltage is above 5V, adding a 10uF cap from the Adjust pin to ground can increase the ripple rejection.

If LPFM means low power FM, even a few millivolts of ripple can cause noticeable hum in the received signal. You can reduce the regulator ripple a number of ways. See

http://www3.sympatico.ca/add.automation/spice/ripple.htm

Best Regards,

Mike

That would be my guess too, though I was still puzzling over the use of "LPFM"
since I thought it was an actual class of FM broadcast license in the US,
so either someone is bootlegging or has a legitimately unlicensed
transmitter.

About a decade ago I noticed the same thing when connecting a DC
receiver to a line operated power supply. Rememberin that I'd read
something about this sort of hum, I looked for the bit. I never
tried a choke, but just bypassed each of the diodes in the power supply
with ceramic capacitors, I forget whether they were .1s of .01s.
The hum I had noticed went away, though before trying it I had
kept adding larger filter capacitors to the output of the rectifier,
without any change.

Since then, I've routinely bypassed the rectifiers in power supplies
I've thrown together. Just last week I noticed some telltale hum
in a power supply I was running a car radio off, and just put a bypass
capacitor across the secondary of the power transformer. Immediately
the hum went away.

A diode is advisable between the capacitor and the output of the regulator.

Patrick,

When I was an FM pirate I had this problem, it was two fold. My VCO regulator wasn't the best, some careful use of a zener and rearrangement of the VCO circuit to make it more robust to supply variation fixed that.

The second problem was a ground loop in the studio to multiplex feed lines, breaking them up with audio isolation transformers fixed that, but effected the frequency response quite a bit. I had to hack the transformer laminations and add a compensation network before the preemphasis networks.

I don't believe in ungrounding equiment to fix loops, it is a hack, and may one day catch up with you, with fatal consequences. You could try running the TX on a gel-cell or similar battery so it floats and is on clean power. But if your VCO is *that* sensitive that supply hum is an issue the transmitted audio quality will suffer anyway.

Another thing to watch out for is RF getting back into the supply and upsetting it. Check the supply output with a scope on AC, is it really the supply that is the problem?

Attack an FM broadcast radio that has been junked with a soldering iron?
That is where I get most of mine from. Over here in Australia we can
get cheap and nasty AM/FM broadcast radios from $2 stores that are worth
more in parts than their face value.

First get a scope or an AC millivolt meter and measure the AC on the DC lead
to see if that's where the hum is coming from. You may be chasing your tale
thinking it's the power suplly. Divide and conquer.
good luck

That will not explain why the light turns on quickly. It takes voltage AND current (ie, power) to light a light bulb or do any other "work."

If the bulb had to wait several minutes for the current to arrive, it would be dark until then.

Yes, you are correct, if the output voltage is over 25V or the
Adjust cap is larger than 10uF. From the LM117 spec:

"Protection Diodes"

"When an output capacitor is connected to a regulator and the
input is shorted, the output capacitor will discharge into the
output of the regulator. The discharge current depends on the
value of the capacitor, the output voltage of the regulator, and
the rate of decrease of VIN. In the LM117, this discharge path is
through a large junction that is able to sustain 15A surge with no
problem. This is not true of other types of positive regulators.
For output capacitors of 25 uF or less, there is no need to use
diodes."

"The bypass capacitor on the adjustment terminal can discharge
through a low current junction. Discharge occurs when either the
input or output is shorted."

"Internal to the LM117 is a 50W resistor which limits the peak
discharge current. No protection is needed for output voltages of
25V or less and 10 uF capacitance."

http://www.national.com/ds/LM/LM117.pdf

This water analogy may be getting a bit strained; but with water, this is no big mystery.

Assuming a valve is open at the far end, water will start to flow out as soon as the pressure wave gets down there. (Pipeline is assumed to be full when you start, natch.) You don't have to wait several minutes for that flow to occur--unless we're talking about the California Aquaduct or something. Of course, the specific water that flows immediately from the far end is the water that's already down there. "New" water from the sending end will take much longer to arrive.

You are free to substitute electrons for water in all this, at your own risk.

4650. Troubleshooting Simple VHF-AM Receiver

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-12-24 22:14:11 UTC
From: Paul Zerkel <pzerkel@insightbb.com>
Message-ID: <T_4O9.496272$QZ.74506@sccrnsc02>
Source record: 39113

Though a ham for some time, I am new to homebrewing and the first project I picked was this receiver. http://www.e-insite.net/ednmag/archives/1997/092597/20di_03.htm I used the PCB from FAR circuits. After many months of procrastinating and collecting parts I finally got everything soldered onto the board.

As the project was nearing completion I discovered the following web site where the original author suggests some improvements; http://www.geocities.com/hagtronics/aircraft.html I have not made those improvements to my project yet. And of course the receiver does not work. I turn it on and I hear nothing, no static, no click, nothing. I am using WalkMan type earphones.

Originally my project had only ~3.3 volts on the Vcc pin. I did look at the schematic and decide that I had a reistor where the zener diode belonged. [Note: the FAR board does not have any labeling indicating what parts go where.] I removed resistor and put 1N5228B (I was unable to find a 1N748A) diode in, I now have 6.1 volts on the Vcc pin but same results.

After starting this project I read in the ARRL Handbook that "receivers are usually buit backwards, starting with the AF amp section" I did not do that in this project because of the order in which I procured parts.

So I am not sure what my next step should be. Is the 1N5228B diode a show stopper? Should I make the suggested improvements before I even try to troubleshoot any further? Should I rip off all the AF amp parts and connect an amp which I know works (I have one of the $12 mini audio amps from Radio Shack)? Do I even need to take all of the amplifier section parts off the board before connecting the mini amp? Is there something else I should be looking for?

As of yet I do not have a 'scope. I may purchase one but I would like to have the confidence in my ability to build a simple receiver before I spend that kind of money. I just am not sure what I should be looking at next or what kinds of tools I am going to need to do so.

Thanks in advance from a middle aged rookie.

Hello all,

Yes, I will try all the things that you all mentioned. I do believe,
like one person said, that it is not so much the power supply as to
the oscillator picking up that 60 Hz.

I did put a non-grounded shield in between the power supply and transmitter
and the hummmmmm definately decreased.

I do believe I will work on that.

Again, thank you for all the great comments.

Merry Chrismtas and a Happy New Year to all.

Respectfully,

Patrick Cambre

You're in a kind of chicken-or-egg situation. The bottom line is
that you have to have, or have access to, at least minimal test equipment
(multimeter and at least a basic O-scope) to effectively troubleshoot
nearly any sort of receiver.

Check your work VERY carefully against the kit plans. Check
for cold solder joints, misinstalled parts, etc. Don't rule out the
possibility that there may be an error in the kit's plans themselves
(though a PC board does dramatically decrease such possibilities).

If you don't have the experience or equipment to troubleshoot, seek
out someone from, say, your local ham radio club that does, and ask if
they're willing to "elmer" you along. Lists of clubs may be found by
digging around at http://www.arrl.org

Good luck.

4656. Ideas for GS-35 tube mounting ???

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-12-25 02:08:31 UTC
From: Douglas Snowden <snowden@peoplepc.com>
Message-ID: <v0hq2g7koudk85@corp.supernews.com>
Source record: 39114

I am starting to collect parts for a Russian GS-35 linear, which is
similar in characteristics to the 8877, but mounting is a lot
different. I successfully mounted a GI7B tube by just clamping the
grid to the chassis and providing air holes for circulation to the
plate. Any experience with the GS-35 out there?
Could I do similar with the GS35? I am guessing I might need to make sure
I cool the cathode are also.

Merry Christmas

Yes, and there are other little things someone could throw together
to help troubleshoot. A signal injector can be handy (though maybe the
harmonics won't be so great at VHF), and made out of a pair of transistors.
Use a radio (scanner or transceiver with wide range receive) to find
the local oscillator; that it's the VHF receiver's local oscillator can
be verified if turning it off makes the signal go away). Find one of
those TTL crystal oscillators that are so common, one that has a harmonic
that will land in the receiver's tuning range, and you have some sort of
signal source. People got by with a lot of ingenuity in the past, and
a simple receiver can be checked out with similarly simple bits of
circuitry.

According to the experts, NiCads are very tolerant of storage:

http://www.powerstream.com/Storage.htm

"Store NiCad batteries in a dry location with low humidity, no
corrosive gasses, and at temperature range of -20 DegC to +45
DegC. Storing batteries where humidity is extremely high, or where
temperatures fall below -20 DegC or above +45 DegC"

"Because long term storage can accelerate battery self-discharge,
and lead to the deactivation of reactants, locations where the
temperature ranges between +10 DegC and +30 DegC are suitable for
long term storage."

"When storing batteries for more than one year, charge at least
once a year to prevent leakage and deterioration of performancedue
to self-discharging. When using a rapid voltage detection charger
carry out charge and discharge at least once ever 6 months."

"The sealed nickel-cadmium cell can be stored in the charged or
discharged state without damage. It can be restored for service by
recharging (one or two charge/discharge cycles)."

I have NiCads that I have stored for years, then suddenly I find a use
for them. They seem to work fine after a couple of charge/discharge
cycles.

Thank you Pete. Acording to Philips datasheets:

TDA1591 -> SNR 76 dB - Channel separation 40 dB
TDA1592 -> SNR 82 dB - Channel separation 40 dB

And for the FM detector?

National LM3189 has 80 dB SNR
Harris CA3189 has 72 dB SNR

do you know anyone better?

Phillips has some pretty good I.F. amp / Detector chips that are being used in some of the high end tuners. I've got a Linn Kudos, and I did open it up, but I forgot which Phillips chip it uses. Magnum-Dynalab has gone to some of the Phillips chips in their newer tuners. They did use the LM4500 in their older designs, but the vendor discontinued that devices. My Belles Research Discrete Class A Tuner uses the 4500, and it doesn't sound as good as the Linn unit. The midrange is reticent sounding, and the mid bass doesn't have the punch of either the Linn or my Luxman T110. The MR78 with the TDA1591 sounds very similar to the Linn. I hope this helps.

The Mini-Circuits are more sophisticated than some of the other offerings that I have seen. The reason that they have the 2nd harmonic suppressed at -30dBc is because they have a tracking filter in the output circuit. Most of the VCOs that I have seen have only 10 or 15dB of 2nd harmonic suppresion. Another thing about the Mini-Circuits devices is their relatively flat KV characteristic over their specified tuning range.
Designing a VCO can be fun, but there are some pitfalls. Sometimes, it is hard to get a monotonic response from the VCO, especially with a wide range unit. I remember one unit that worked fine in the breadboard stage, but once the PC board was laid out, the strays were reaking havoc on the circuit. As you varied the tuning voltage up in value, the unit would increase in frequency, but at some tuning voltages, the unit would start to tune backwards, only to tune in the proper direction as the tune voltage was further increased.
One way that you can characterize a VCO is to hook up a Network Analyzer to the input tuned circuit of the circuit, and look at the S11 parameters. Setting up the analyzer for a Smith Chart display, you can look at the Unity Gain Circle. There will be a frequency range where the VCO will exhibit negative resistance; it this range is contigous, the VCO will be fine, but if there are loops in the displayed response, you will not get monotonic tuning response.
The whole point of this is that it is easier to purchase a VCO from a reputable manufacturer such as Mini-Circuits. I have also used some of the units from Magnum Microwave, and they have been ok, but the ones from Vari-L have left something to be desired. Neither phase noise nor harmonic suppresion were as good as the Mini-Circuits devices, and on top of that, the Mini-Circuits VCOs were priced much cheaper.

What a preposterous statement. With a basic second hand scope you will need 20 minutes (not 2 years) of instruction on electronics. If anything, the scope will be a real learning tool for persuing your studies.

Having taught freshman engineering labs I can assure you that the engineering students meet Mr. O Scope the first week of school, not in their Jr. Year.

There are many things you can do with a scope very early in your
training. There are a few others which will take more training to do.
Not a proper electronics lab without one, IMO. You probably do not
need a highly sophisticated one to start.

Many people have trouble learning electronics because it is hard to
visualize (electrons are tiny). An oscilloscope as a learning tool is
invaluable for this, especially for learning AC, RF, and digital
circuits.

Work the flea markets and find a boat anchor, manual style O'scope.
Not big bucks unless you go for the high-end models.

Happy trails,

4671. Heathkit SB 230 Help with initial checks

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-12-26 01:30:10 UTC
From: GAEL79@peoplepc.com
Message-ID: <3de1a5d2.0212251730.31cd8766@posting.google.com>
Source record: 39136
Cross-posted to: rec.radio.amateur.boatanchors,rec.radio.amateur.homebrew

Hello All,

I am new to this, and this is my first Amplifier, so be gentle with me (HI-HI).

I have pieced together a Heathkit sb 230 HF Amplifier and am having proplems. I did not know the history of these parts, so I was very detail oriented (you might say anal retentive) about checking all the parts and taking several days to go through the complete assembly manual to ensure all was assembled correctly.

Here's what happened:
I am working the initial checks here, with no coax, radio, antenna, just the stand alone amp.
I am on page 88 of the assembly manual. Meter zero - GOOD. Check #1 - all GOOD. Check #2 pulled wire from pin 3, cover back on, this part goes good, hi temp light works. replaced wire on pin 3, replaced cover. Plugged in line cord. Turned amp. on. I got the delay light, and it went out within the 60-90 second window.

Turned the meter switch to exciter only. The "exciter" light works only in the exciter position, as it is supposed to.

Now is when things go wrong. I switched the meter to plate, they tell me to find a piece of "hook-up wire" to short out the relay phono socket. So, I found a wire and I am just starting to lean over the cabinet, to reach the relay socket (I never actually shorted the relay socket out), it is now 15-20 seconds after I swithed to plate, and I see a spark, through the cabinet top in the area of the relay (RY1), I blow a house circuit breaker, also the fuse in the back of the amp blew.

I must state at this point, the fuses I bought were .75 amp fuses, but not slow blow. I hope that explains my following actions.

I removed the cover, did not smell anything burnt or see any visual damage after a detailed inspection to both sides of the amp.

O.K. perhaps the fuse was faulty, I tell myself, or the fact that they call out for slow blow, and I could only find fast blow fuses in the correct amperage. Maybe the flash I saw was the relay contacts???...

I talked myself in to trying another fuse. This time It took about 5 seconds (it did not happen instantly), I had what sounded like fire crackers, and could see several sparks dancing in the rf enclosure. (I am sure it was arcing, Going on, I could see it through the top at

C15, in the rf enclosure.) Quickly, I shut off the main power switch. This time I did not blow the house circuit breaker.

Of course the fuse blew again. This time after removing the cover, I removed the RF cover to find no arcing spots on the capacitor plates (guess I am lucky). I did however, find R17, 33ohm, 1 Watt resistor blown to bits. This resistor is located just off of the grid of v1.

About the 8873 ceramic tube. The filament pins 5 and 6 show continuity. and the grid pins (4,7,11) are not shorted to the cathode pins (1,2,3,8,9,10).

Does the fact that that resister blew, and the fuses blew, mean I have high grid current? Did the arcing in the rf enclosure happen because the tube was energized, and no dummy load was connected to the amp?? Is this amp trying to amplify power, when it is not supposed to? Does the "fireworks display" in the rf enclosure at least prove the tube is good or amplifying like it is supposed to?

I have no idea what to do next. Anyone who could point me in a direction, I would be greatful.

Thank you for taking the time to read through this!!!

73,

Scott KC9AWN

P.S. I posted this on E-Ham.net a couple of days ago. The responce I got back was something about checking for para. oscillations? Could someone please explain to me?

Thanks,

Scott

4672. New simple LC filter design program

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-12-26 02:08:16 UTC

PROGRAM "LPF_HPF.exe"

Most filters consist of one or more cascaded, simple, 3-component, T or Pi sections and are used in a multitude of applications where pass-band ripple, frequencies of infinite attenuation in the stop-band, exact impedances matches, etc., are not of consequence.

This easy to use program calculates component values of high-pass, low-pass, T and Pi, basic filter sections. Internal filter loss is neglected. Operating inconveniences which may be present in more complicated programs can be avoided.

Filter response vs frequency is in terms of dB insertion loss between Ro terminations for 1 to 5 cascaded sections. Frequency range is from audio to VHF.

Download in a few seconds program LPF_HPF.exe from website below and run immediately.

As posted by others, you have the chicken and egg situation of no test gear.
From memory these chips run on 8V - I dont think you would get much at 3.3V
Download a copy of the datasheet from from the web - I presume it will be
found somewhere.
If you listen to the normal discriminator output you should get FM "hash" -
this could be a good source of signal for testing.
You could invest in a digital multimeter and check voltages at VCC and check
continuity of *all* the connections and the correct placment of every single
comopnent. and check whether there are any shorts to ground. The zener is a
rather odd configuration - assuming the chip can stand 9V (check datasheet)
you might omit it. If the wrong diode was present (you said you did not have
the correct one) it might block your supply altogether. Try touching the
RSSI output with a finger - do you get any hum in the headphones?
Of course, if you had the right gear, you could inject a 455 KHz signal into
the IF. It might be worth making up a simple oscillator using a ceramic
resonator or maybe taking off the IF from another receiver - say a cheap AM
portable etc etc

Source record: 39139

100% correct.

A simple key is a simple key. You make the dits. You make the dahs.

A single paddle key is a single paddle key. With it, you can use an electronic keyer, but you can only make the keyer send a dit, or a dah, or a string of dits, or a string of dahs, depending on which side you push that paddle to.

A double paddle key is a double paddle key. With it, you can use an electronic keyer to send a dit, or a dah, or a string of dits, or a string of dahs, or di-dah-dit, or dah-di-dah, or dah-di-dah-dit, or dah-dah-di-dah, etc. Those last four are essentials of iambic keying, where much of your operating is not just swinging a paddle from side to side -- it's squeeze keying. One paddle sends dits, and the other sends dahs. And you can intermingle them any way you like.

A bug is a mechanical precursor of electronic keyers. A typical bug will give you repeated dits by pressing and holding one paddle, and you make the dahs yourself by pressing the other paddle repeatedly. You don't need any electronics; just plug it into the transmitted keying circuit.

To me, squeeze keying is the greatest thing since sliced bread. It takes a little practice to learn, but only a little. My fist is a sloppy mess at 20+ wpm with a straight (simple) key, a single paddle is too tiring, and I never learned to send properly with a bug. But squeeze keying with an iambic keyer is wonderful.

> got back was something about checking for para. oscillations? Could
> someone please explain to me?

Parasitic oscillations.

the fact that the grid resistor was blown to bits, indicates to me that there might have been some vhf oscillations, that probably started because the resistor had possibly changed values, or simply wasn't large enough to handle the current being drawn through it, when the amp was place in the 'operate' mode (by closing the relay).

Check out the characteristics of the 8873. You should find out what the static current would be on the grid, while voltage is applied.
Since this is grounded-grid, there won't be any bias supply, -but- the grid leak resistor will still have some voltage across it, and there will be some grid current, at rest (grounded grid amps, are still run in AB1).
Whatever that voltage is, at the amount of grid current being read, will determine how much power handling capability is required of the resistor.

Merry Christmas - hope it was good.
-Geoff

First, Thank you to everyone for replying so quickly especially during the busy holiday.

>>From memory these chips run on 8V - I dont think you would get much at 3.3V<<
The 3.3 volts was what I had when I had a resistor installed where I now have a zener diode. (again the PCB has no labeling) so I was doing my best to deduce from the traces & schematic where components belonged). After I replaced the resistor with a diode, I am now getting between 5.5-6.1 volts on the Vcc pin (depending on freshness of 9v battery).

According to the SA605 datasheet, the Vcc power suplly voltage range is 4.5v min and 8.0v max. The absolute maximum is 9 volts. So I am thinking 6 volts or should be reasonable on the Vcc pin.

I do not get a hum in the headphone when I touch the RSSI pin with a finger.

I am not giving up on this. I do have a multimeter but no O-scope. Actually I discovered that my local junior college is offering Electronics 100 in an evening class this Spring semester. I signed up for it (I did once before, but the evening class was cancelled that time). If this class happens I may have some access to an oscilloscope soon. I have also been watching ebay pretty closely lately.

You are absolutely correct. In spite of the almost universal usage of
calling a dual paddle mechanism an 'Iambic keyer', there is no such thing.
It's just a dual lever or dual paddle key. The 'Iambic' (or Ultimatic) part
is in the elctronic keyer circuit - not in the paddles. :)

Here is a small radio controller to make an HT into a foxhunt
transmitter:
http://www.byonics.com/piccon/piccon.html
Note that this is a kit, but a pretty simple one. Depends on your
matchbox, but this will fit. There are some tiny, lower powered HTs
out there. You should be able to find one that fits into the palm of
your hand, less antenna.

Transmitting on 2M requires a licensed control operator, and
compliance with the station ID rules. The device does not require
licensing.

Happy trails,

Scott,

First - tell us a little more about your amplifier. As I recall, the SB230 was introduced in 1975, and produced until the early 80's. Unless you were r-e-a-l s-l-o-w and very anal retentive, it shouldn't have taken you 20 years to assemble this Heathkit. What's the background - all new parts? Sealed box? Disassemble and rebuild from scratch?

Second, there were problems with the SB230 and self-oscillation, and during its life we included several versions of parasitic suppressors to prevent VHF self-oscillation of the tube -- resulting in the types of behavior that you describe. Depending on when your kit was manufactured, you may have an early model with a ...less-than-optimal... parasitic suppressor on the tube.

My memory is a little shaky on this - that was about 30 years ago for me. But there is a Heath mailing list and Heath reference sites on the net, with on-line technical bulletins for kits like the SB230. You should check those out before re-applying power to the SB230.

In case you hadn't noticed, the 8873 tube sells new for about $700 [it was $35 in 74 when we designed the amplifier] , rendering the amp all-but-useless in the event of a tube failure (and used 8873s are scarcer than hen's teeth). So, you should take great care when troubleshooting this problem less you blow the tube.

that's all fine...but what makes one tube a better osc thanthe other.

the 5763 has higher transconductance...but that's not really the deciding
factor, is t? Or, are the differences buried in the performance charts?

Patrick,

You are probably well beyond this stage, but I happened to come across a beginner's FM transmitter page you might enjoy reading. It compares several different methods and has some specs for frequency drift with warmup and antenna orientation:

Thanks for the reply! Both my TR7 and R7 sounds OK on 10 meters, but they are
late versions. Looking at early and late service manuals some things have
changed, but the main change seem to be that more shielding is used in
the later versions. Probably bad shielding and bad grounding can cause
ill effects in the 7-series.

The outboard VFO came in two different versions, one PTO-version, the same
that is used in TR7/R7, called RV7, and a synthezised version called RV75.
The main use of these are to reduce the drift. I do not think that they will
influence the phase noise to any great extent.

The LO cleanliness is something that I intend to look at also. I'll bring
the R7 to my work place and take a look at the LO on a spectrum analyzer.
I am not sure how to improve the LO, besides doing a total redesign, but I
will take a look at it.

The LO port seem correctly terminated (a 2N3866 amplifer followed by a
-3 dB pad, then the mixer) I am a bit unsure about the IF though. It is
feed through a PIN-diode (MPN3404) switch to an amplifier (J310) (the
amplifier is used both in RX and TX, the diodes are used to reverse the
signal path, switching between RX and TX) Perhaps one should add a
diplexer here to terminate the unwanted mixing products into 50 ohms?
Reading "Solid State Design for the Radio Amateur" by Wes Hayward and
Doug DeMaw, this seem to be a good idea. Any comments on this, anyone?

I actually did this on my former TR7. I changed the four diodes and
four resistors to a HP5082-2830 ring mixer. I did not do any
measurements, but it sounded clearer after this.

<< Turned the meter switch to exciter only. The "exciter" light works only in the exciter position, as it is supposed to.

Now is when things go wrong. I switched the meter to plate, they tell me to find a piece of "hook-up wire" to short out the relay phono socket. So, I found a wire and I am just starting to lean over the cabinet, to reach the relay socket (I never actually shorted the relay socket out), it is now 15-20 seconds after I swithed to plate, and I see a spark, through the cabinet top in the area of the relay (RY1), >>

Scott-

It sounds as if you have high voltage at this point, but no RF drive and nothing connected to the input of the amplifier. Are you supposed to have high voltage before the relay is energized?

If there is an parasitic or self oscillation, it could be because of having nothing connected to the input. Connecting 50 Ohm dummy loads might help for troubleshooting, both on input and output.

I don't think there should be any control grid current under no-drive conditions unless the grid was driven from a positive voltage source. That might happen if a coupling capacitor from a previous stage was leaking or a bias supply had its rectifier connected backwards.

Good Luck.

multi-pole passive filtering works well. one has to be careful of phase margin in the added/modified filters. you could end up with a permanently whistling osc, regardless of dial settings.

>
> The LO cleanliness is something that I intend to look at also. I'll bring
> the R7 to my work place and take a look at the LO on a spectrum analyzer.

lots of spurs might be visible. be careful not to introduce outside signals as accidentally-injected into the rig.
gives false results. prevents chasing a ghost signal.

but, at what level does one deem a clean LO? it all depends on what you ultimately want from the rig.

better bypassing and PS filtering can go a long way. remember, these are consumer electronics rigs.

>
> The LO port seem correctly terminated (a 2N3866 amplifer followed by a
> -3 dB pad, then the mixer)

a six- or ten-dB pad would be better. reflections would be reduced in level by twice the isolation. a ten dB pad would reduce the reflected component (back into the LO or IF port) by 20 dB. that's a power factor of 1/100.

> I am a bit unsure about the IF though. It is

i've done this but "heard" no measureable performance increase (both with 2 meter and aircraft band converters). it could be useful, tho, in a strong signal/ crowded signal environment. diplexers are quite easy to build. might be better bang-for-the-buck to add a ten dB pad right at the IF and RF ports.

again, the end results is...what level of measureable performance do you want the rig to perform to?

I got the amp from a garage sale, in piles of parts. I am lucky
enough enough to have an old tv/ham store in town for some of the
resistors, caps etc. that were missing. I wish I new more about the
amp. but I don't. I can tell you that I went step-by-step through
every page of the manual and (NOW) it is together correctly. (I am a
Avionics Technician by trade) Whether the tube is any good is anyones
guess, but it passed the coninuity test on the heater pins, and the
grid pins are not shorted to the cathode pins. I would also assume
that the tube was good, or I would not have had the "fireworks" in the
rf enclosure.

Forgive my ignorance here but...

Should there be any oscillations at this point? please understand that
I have no experiance with HF amps. I had "nothing" hooked to the amp,
and am doing the initial checks. I didn't have "anything" external to
the amp hooked up. No radio, no antenna, no dummy load, nothing. Your
operators manual does not tell me to hook up anything to the amplifier
to do these initial tests. I did not even get to short out the relay
connector, per your manuals instructions, before things went bad.
> My memory is a little shaky on this - that was about 30 years ago for me.
> But there is a Heath mailing list and Heath reference sites on the net, with

I have looked to no avail. A ton of information on SB200/201 and
SB220/221 and SB1000's, but no info on SB230's. If anyone knows of a
source on the net, I am all ears.

Yes, I did notice that. If it gets to the point where I have to buy a new tube, I will modify the amp for a different tube and provide a blower for cooling.
>

>
> Why?

The 5763, along with various video pentodes, were preferred as
oscillators in transmitters because, thanks to their high gain and
good grid-plate shielding, you could get a fair amount of power out of
them with minimal crystal (or tuned-circuit) current. The goal was
usually to be able to drive one of the "typical" medium power RF PA
tubes, such as the 807, 6146, 6DQ6, ect., directly. OTOH, I once saw
a circuit where the pentode section of a 6U8 was driving two 6146s to
full grid current, so I've often thought that the use of such big
oscillator tubes was less a technical issue than a case of "couldn't
hurt, and doesn't cost any more." Just MHO!

It really depends on your sources, and the blocking voltage on the
cathode. I would have chosen VN2408, but since I haven't seen the
circuit I am not aware if low capacitance in the device is important

Hi.

150V on the plate...so, when the cathode is disconnected, the "instantaneous" cathode potential would be about 150v.

Cool thanks. What I'm basically looking at using it for is locating rocket kits after they land in the scrub and get lost. It would be fitted inside the tube somehow, which is usually pretty small. Thanks,

David

Lots of equipment use 6AU6 (EF94), but I have good experience with
6DA6) (EF89). But my preference is 6U8/6U8 or 6BL8/ECF82. Used the
latter in my FL-dx-500 (triode as oscillator and pentode as buffer),
but it really depends on how much work you want to do

Ah, high tech hide and seek. A simpler beacon may do it for you then,
and you may be able to find kits to do that. You can't be the only
person looking for their model rocket.

You may still want the foxhunt controller to practice with.

Happy trails,

Pete, this sounds reasonable. What parameters are they matching on the HCDs and what is a source for these matched components?

Thanks in advance for info.

Steve

Nah. The grid is grounded, so conduction stops at the cutoff voltage,
perhaps 40 to 60V. The transistors in an ordinary PC power supply can
handle over 300V and several amps. Just disassemble a dead power supply
and get them for free:)

You probably only need 5V or less to bias it off. Particularly if the
oscilllator is keyed, it is no advantage to have high voltage, so a
voltage divider is the best

The very best scope you can get is the TEK 7904. Mainframes are cheap,
and you can get plugins to do just about anything - dual channel 200MHz,
single channel to 1GHz, 10uV/div with variable bandwidth up to 1MHz,
sampling plugins to 12GHz, tdr, spectrum analysis, even a transistor
curve tracer. No modern scope can match the versatility.

I see John Bau has a 7904 4-slot 500MHz scope mainframe listed on his
site for US$235.

http://www.users.qwest.net/~jbau/tstequip.htm

I've bought stuff from John and recommend him very highly. I convinced a
friend in Germany to get a 7904 and a bunch of plugins. Everything
arrived in good condition and he is very happy with it.

About the only problem you may have is the electrolytics tend to dry out
after several decades. I replaced one in the power supply of my 7854
recently. I happen to have all the manuals, but didn't need them to
disassemble the scope and get at the caps. A replacement cost about $2.00
and it works good as new.

Of course, the 7A29A has 1GHz bandwidth and was intended for the 7104,
but it works fine in the 7904 and 7854 which have lower bandwidth.

You are dead on! I looked at the specs for 6AU6WA the on Frank's tube site http://www.mif.pg.gda.pl/homepages/frank/vs.html

The grid #1 voltage for Ib = 10uA is -4.2 to -6.5V.

You have a very good memory. I haven't touched one of those since about 1967!

I have also done that over the years. Doug DeMaw described the technique of connecting .01uF caps across each of the rectifier diodes, so that they would not rectify RF. He stated that this would eliminate common mode problems in DC receivers. I took things another step, by bypassing each leg of the secondary of the power transformer to ground with a 1uF NP cap. This eliminates the switching noise coming from the diodes, giving a power supply that is "quiet" all the way down to 10kHz. I never did realize why some portables would always seem to receive some kind of flourescent light type of interference down below 600kHz. I discovered this bypassing technique out of desperation!

I bought a batch of them when I was working at Rockwell-Collins, from their Inventory Disposal store. They used to sell components for $1.00 per pound. It was pretty funny, when you would have a bunch of stuff, and the cashier would put everything on a scale.
As far as the matching of the devices, these were done at HP. I had around 50 sealed static dissipative bags of these quad sets. Most of them when the way of the hamfests, but I did manage to keep some of them. One of the fellows who purchased them from me told me that they were matched to within .01dB of each other. I am not sure what he meant, but the HP label on each bag states them to be matched sets.

Source record: 39082

There are three RF transformers in the 3 stages of the Rx RF amplifier: AE;1st RF;2ndRF. Primaries are untuned, secondaries are tuned. Secondaries are in fact part of grid circuit, primaries are in anode circuit (except AE of course where primary goes to aerial), and of course one side of the primary windings and secondary windings is "dead" ie, not "hot" rf wise.

Question: If I reverse which end of secondary or primary is "dead" (or "hot") will it make any difference? Or should "dead" side of windings be sort of opposite or near each other on the coil fomer? TIA.

Your question is not clear to me. Tell us again what you want to do in another way and what you think it'll accomplish.
Many years ago when I was a TV tech we sold a new TV to the Mayor, he bought it because his wife liked the cabinet but he didn't like the picture. But depsite his complaining he ended up with the nice cabinet and snowy picture. After a few days he came back compaining about the picture and he couldn't understand why the expensive cabinet didn't play as well as the cheap cabinet. On service calls the techs found that if they installed a "hot" 6BQ7A in the tuner, the picture would be less snowy, but the 6BQ7s would only stay hot for a week or so. The chassis were not interchangeable and the factory was slow in repsonding. To make a long story short I yanked the chasiis took it back to the service bench and after countless hours (no good test equipt) I discovered that the first IF transformer was installed backwards in the can. The polarity dot was correct on the tabs but the coils were miswired inside the can. After I changed the transformer the picture was superiior to all the other sets. I became the Mayor's and shop owner hero!

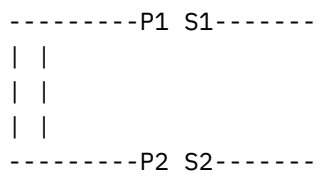
TFMR



Say, physically, P1 is at same end of coil former as S1. If S1 is the "hot" side of the secondary, does it matter whether P1 is rf "hot" or "cold"?

[snip]

According to schematic diagrams reversing these connections will make no difference.

But then we all know that all things are not shown on schematic diagrams.

In practice the inter-winding capacitances, which are a "stray" unwanted parasitic
effect, between the winding ends and the other winding will be different. The
inter-winding capacitance is invariably slightly larger with one end grounded than
with the opposite end of the winding grounded. Ideally, the inter-winding capacitance
should be zero in either case, but it never is!

Why should we care about inter-winding capacitance?

With an *ideal* transformer having zero inter-winding capacitance, the so-called
common mode rejection is infinite, but with such capacitance it is not. Hence
unwanted common mode signals are coupled across the transformer. Depending
upon the application, low common mode rejection ratio [CMRR is usually specified
in dB] may or may not cause a problem during operation. It's usual effect when
evident is to introduce spurious unwanted signals at a low level.

But then the solution is cheap, eh? Just connect the *correct* end to ground!

How much does this improve the common mode rejection ratio? Often it can make
improvements of as much as 20 - 25dB in the CMRR. Not insignificant if you
encounter a spurious problem.

Sometimes inter-winding capacitance is partially mitigated by use of a grounded
Faraday shield between windings. Even though this kind of shielding reduces

the
effects of low CMRR, connecting the *correct* end of the winding to ground
still improves the situation, and the cost is the same. Cheap, just connect
the *correct* end to ground.

In critical applications, such as instrumentation, etc... knowledgeable
design
engineers always specify the correct ends of windings for ground connection.

How can you tell which end is correct if they are not marked. If possible,
a
simple visual inspection of the winding layups may reveal which end is
closest
to the other winding in question, and hence which end has the highest inter-
winding capacitance, this end should be grounded, leaving the lowest
inter-winding capacitance to couple the unwanted high frequency spurious
signals.

"In theory, theory and practice are the same, but in practice they are
different!"

There are variations of how things are wound.

Where there are two single layer coils the ends that are rf "cold"
should be at the same end?

If one pile wound coil is atop another pile wound coil, the junction of
these two coils should be rf "cold", meaning primary and secondary coils
ends that come close at this point should both be connected to rf "cold"
parts of their respective circuits?

If one pile wound coil were atop a single layer coil, the pile wound
should, for best results, be at one end of the single layer coil and at
that end the single layer coil should be connected at rf "cold", whilst
the pile wound coil end nearest the single layer coil should be at rf
"cold"?

[snip]

Yes indeed, I agree.

All of those suggested connections use the lowest inter-winding
capacitance connecton.

The central idea in CMRR reduction is to minimize interwinding C.

A general formula for the capacitance C of a capacitor
[that's capacitance of a *condenser*, for *fogeys*] is:

C = eps*A/d

Where eps is the dielectric material factor, A is *effective* Area of
the capacitor plates facing each other, and d is the distance between
them.

Usually with inter-winding one tries to arrange for the observed
capacitance between windings to be as small as possible. In many
cases, it is the distance d between the primary and secondary windings
[ends] that should be maximized to minimize C.

Concerning two single layer coils.

TFMR

```
---------P1 S1-------
| |
| |
| |
---------P2 S2-------
```

Say P1 was rf "hot" and S1 rf "hot" P2 and S2 at rf "ground" or rf "cold". Capacitance between P1 and S1 conveys an unwanted current over to S1. But if S1 was at rf "cold (decoupled to chassis) any current transfered by capacitance would go to ground. Is this contradicting what we thought about desirable transformer connections for single layer coils?

4726. Ringmixer LO level?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-12-27 17:01:24 UTC

Source record: 39090

You would still need about 30 mA peak to peak, but
the voltage required would be twice as much. The
input impedance for the LO port on an SBL-1 is
actually somewhat less than 50 ohms, so with the
doubling of voltage, you would end up somewhat
greater than 50 ohms. It's not critical; you can still
use a 50 ohm LO source.

Why do you want to do this? If it is to get higher
dynamic range, you should know that the conventional
way to do that is to add reverse self-bias to Schottky
diodes by putting a parallel RC circuit in series with
each diode.

Hi, Pete.

I used an SRA-1 mixer with 6dB pads on LO/IF/ RF ports, into a Collins 75S3B rx, the IF was 28.2mHz, and no 2m preamp. The minimum discernable signal w/o the diplexer was better than -150dBm. I used a 10 dB attenuator on the output of the HP 608D, to get below the minimum -140dBm dial marking.

Based on this result, I didn;t use anything special.

Hi,

I'm having some problems understanding a bias circuit for a 250Watt
powermodule. To be able to discuss about the circuit, I did put it on
http://www.angelfire.com/space/schematic/amp_circuit.jpg
The transformers T1 and T2 are needed to transform impedances. I guess D1
is used to protect the high power transistors.
I'd like to get to know more about the bias circuit, that consists of Q3
and Q4. R3 is a variable resistor, R2 is a 10Watt 50 ohm resistor and R1 is
a 1800 ohm resistor. How does this circuit work ?

Regards,

Mario.

[snip]

I don't understand [exactly... specifically] what you mean by
"rf ground", "rf cold" and "chassis".

The fact that you use so many terms for what should be the same thing,
at least in my mind, indicate to me that perhaps you are not sure of
where "ground" is.

I believe you said that S1 was both "hot" *AND* decoupled to chassis!

I'm surprised by that! Do you mean that both are at rf ground? If so then
where do you expect the signal coupled from P1 to S2 by the magnetic
coupling to go if it's been decoupled into ground? The signal at S1
with respect to "ground" and/or "cold" will be zero! What?

rf cold, ground, chassis,...

What exactly do you wish to do with the signal coupled from P to S? i.e.
where does it go next? And how is it to be handled?

Rick

Thanks for an interesting reply. No, I wouldn't do that, or I wouldn't think of modifying an already working device. But I've used 1N4148 mixers on some occasions, and just had to find a way to put the words to get the reply I was after. I wasn't aware of those '30mA', but I was told that better IMD could be achieved by connecting two 1N4148 or other type in series for each place. On the other hand I have a douzen CM-1, SBL-1H, SRA-1, MD108, some SL6440's, 74HC4066 and other types available in the shack, so I don't dream about making my own mixers, I was just curious

The problem is more like that it is difficult to use all the components I get from friends around the world, but now I have got another argument to evaluate some of them

I don't know the HP608D, but suppose you already are aware if the
output atenuator is good for signal levels down to -140dBm? I wouldn't
rust my Wavetek model 3001.

Before being aware of the misery I spoiled the 70cm transverter, hi,
but model 3001 isn't safe below 1V if the equipment under test isn't
well screened.

It is a definition sometimes used with Hi-Q tuned circuits in
tube-circuits where one end of the coil were supposed to be better for
ground side than the opposite dependent on the way you wind the coil.
You usually placed the link on the cold side. But for transformers on
toroid cores it is no such things, you just ground the side of winding
which gives the desired phase relationship.

I thought I was using commonly used terms. Placing a capacitor with low
reactance to rf at P2 and S2 would make these ends effectively connected
to chassis for rf purposes. You know that of course. I just call P1
and S2 at rf "ground" or rf "cold", I could say rf "chassis". Opposite
would be rf "live" or rf "hot". You could touch P1 and P2 without
detuning the resonant circuit if the primary or secondary were parallel
tuned circuits.

So, if you wound two single layer coils, primary and secondary one above
the other and decoupled both at the same end, then that looks bad to me,
because if P1 and P2 are both rf "hot" rf current can leak
through the capacitance between P1 and P2 ends and get into the
secondary circuit. Whereas if P1 was rf "hot" and S2 was at rf
"chassis"
any unwanted current passing by capacitance from P1 to S2
(assuming the ends were the vulnerable spots because they are most

rf "hot") would go to ground at P2. But, also wanted signals at the resonant frequency would also want to leak through and go to chassis at S2. However it could be that C is so small between P1 and S1 that little signal at the resonant (say HF) frequency passes by way of capacitance, ,but unwanted (say VHF) signals would more readily pass. Thus if this were the case it's best that if P1 is rf "hot" S2 be rf "cold"

But maybe with regular rf rx amplifiers, in practice, unles there is a local VHF Tx about, it matters little which way the transformer connections are made.

Check some of the newer chip families. Some of the 74/54 'AS' and 'F'
series will probably work in that range. You may have to test for chips
that work at frequency. i.e. Specs may guarantee 100 Mhz with typical
speeds 120 to 140 Mhz.

[snip]

This is true.

If your application is not bothered by common mode signals, then it simply doesn't matter which terminals you connect to ground.

The connections on transformers are only important if they make a difference in the operation of your application. Try it one way and look for disturbances,
then try it the other way and look for disturbances. Then use the connection
that results in the least disturbance to your circuit operation. If it makes no
discernable difference, which it often does not, then you don't care.

When it does make a difference, then it is always the inter-winding capacitances
and the finite common mode rejection that causes the problem.

In many/most typical application circumstances it simply makes no difference.
That is why most such commercial transformers are not marked with "polarity" or "start and finish" marks.

In extreme cases, such as with instrumentation in the presense of very strong
common mode signals, the winding geometry of the transformers are specially designed and manufactured to reduce and/or equalize the inter-winding capacitance
to enhance the common mode rejection ratio.

I have had good luck with the MC12080 chip from ON Semiconductor. The cost is about $4.00 from Newark Electronics. This is a surface mount part. The input frequency spec is 100 MHz to 1.1 GHz, but I have used it successfully at 50 MHz.

Message-ID: <3E0D361E.352DEEC6@northwest.com>
Source record: 39011

Q3 provides the current used to bias Q1 and Q2. Q4 adjusts the bias point for Q3, which sets the drive current for Q1 and Q2. C9 appears to be a hi-freq rolloff feedback cap. What is its value?

D1 is in parallel with the Vbe diodes of Q1 and Q2. It is likely to maintain a specific Vbe during hi-temperature operation (to inhibit thermal runaway).

My translation on the circuit...

Hi Larry,
I do like those Mini-Circuits mixers; they do work very
well. It sounds as if things worked out for you. The one reason that I do like the SRA-3, TUF-3, TFM-3, SBL-3, and TAK-3 series is that the "3" series have approximately 4.75dB SSB conversion loss, while the "1" series have approximately 6.5dB. When not using an RF stage, it does help a bit. Will it make an audible difference on the HF bands? Probably not, but still, it is nice to have that extra sensitivity when using a whip antenna. Also, the "3" series are good down to 25kHz, while the "1" series are specified down to 500kHz, so the "3s" are good for LW reception. I believe the SRA-5, etc. are good to even lower frequencies, but I would need to check my databook on that one.

Pete

Thanks all for analysing the circuit.
Ok, I think i start to understand it. Could a good biascurrent be measured
by measuring the R2 voltage ? The only way to bias the whole thing is via
R3, so i guess the voltage across R2 can be used to determine the ideal
biaspoint of Q1 and Q3, no ?
The push-pull transistors are BLW96's.

He did not ask for copies. He asked for the disks. No one running Word 97 would give up his disks (re-install after a crash eg) so if someone no longer uses 97, has purchased Office 2000 (not an upgrade), then he is free to sell/give his disks to anyone he wants.

There are several ways to mount the GS35b. A finger-stock grid ring is not very successful because of the enormous weight of copper in the anode cooler. Clamping works well, either direct to the chassis with four L-brackets (like you would mount an Eimac air-system socket, only bigger) or with a turned ring as shown at:
http://www.6mdx.eurobell.co.uk

For cooling, it's best to blow air in *above* the chassis, and let most of it pass through the anode cooler. The hot air should go straight out of the amplifier through an exit chimney.

The cathode area requires much less cooling than the anode, and this can be adequately done by four holes of about 0.75in (20mm) diameter, spaced close around the grid clamp. Cool air flows downward around the cathode connections, and then exits through a screened hole in the base of the amp (with a much bigger open area than the four holes in the chassis).

There are many other ideas at www.nd2x.net which is probably the world's best site for amplifier designs using Russian tubes.

Source record: 39024

Hi,

How does one derive model parameters as required by SPICE from
manufacture's datasheets?

thanks

Faltered? Maybe. Failed? No way. I still use WP. Have been since
DOS ver. 5.1, and I've got not the slightest intention of switching.

I don't care who makes it. At its core feature set, WP still runs
rings around Office for technical writing.

But, then again, that's a whole 'nother story. I'll not let the
topic drift get any further than that on my part.

hi, mario. remember, the bias point (drive current) for q3/q4 sets the output current drive for q1/q2. not quite the same beast as grid voltage for a tube.

we're looking at currents here, not voltage. you could work backwards, knowing a basic Vbe is about 0.6volt. using kirchoff's voltage laws, and make a rough estimate of what current values are involved.

word2000 doesn;t save in the same format as the older versions.

if i save a Word 2000 doc file "AS WORD97," then Word 97 doesn;t recognise
the translated formats from Word 2000. so, i'm downgrading.

that's the crux of the issue.

>circuitry.

I once knew a totally blind guy who did radio repairs for a living. He developed all sorts of other clues as to where a circuit was going wrong. Quite remarkable. Another chap I knew (sighted) had *no* knowledge of radio whatever but still had an intuitive grasp of how to build and repair them. Seems to be an inexplicable and very rare gift in just a few people, though.

I've been using Office 97 as a standard between workplace and home for
the last few years, although I have 2000 in the box around here
somewhere.

The feature of saving in older formats has always worked fine for me,
but I haven't gone to Word 2000. Other than losing the benefit of new
features, it should work fine. At least it did with the significant
file format change from Office 95 to 97.

You might want to check with the Microsoft website in their "Knowledge
Base" as well as getting any patches issued after your CD was burned.
Happy trails,

I'm planning an AM broadcast band reciever, with the purpose of DXing very distant stations. I'd like to have a few modes one of which is AM stereo and Exulted carried sideband select. Anyone know of some documentation on how the various AM stereo systems work and can be demodulated? Secondly does anyone know how you can use the carrier and one sideband or only one sideband to pick up the station? The purpose of this is to dig out weak signals from more powerful local ones. Thanks,

David

Larry,

Actually what i meant was to measure the voltage across R2. This gives you
the current through R2. So, this will allow you to calculate more or less
the other currents.. Couldn't you assume that half of this 'R2-current'goes
more or less to each push pull transistor ?

With some difficulty. If they are just transistors in something like an AF circuit you can usually manage with a generic device and simply add things from the data sheet like like hFE. Try posting this to sci.electronics.cad. There are *lots* of SPICE experts lurking there who delight in this sort of question.

You could use a CPLD and put all your other digital stuff into it (like most of a PLL). They go up to 200 MHz or more. This approach is getting quite common.

Source record: 39037

A lot of manufaturers provide SPICE model parameters for transistors and diodes. A search of the manufacturer's web site for "SPICE" should get you to the right spot. For those that don't, you can derive some of the parameters from the data sheet and curves. The process is simple for some parameters, complex for others. An excellent book was written on the topic. Although I'm sure it's long out of print, there might be a successor to it, or you might be able to find an old copy. The book is "Modeling the Bipolar Transistor" by Ian Getreu. It was published by Tektronix in 1976, and carried Tektronix part number 062-2841-00.

For many or most analyses, a very simple model of a transistor or FET, with only hfe or gm, ft, and capacitances, read pretty much directly from the data sheet, will give adequately accurate results.

Hello CDR,

I did have exactly the same problem with my TM-742E, due to a short-circuit in the microphone connector. I think a (SMD) fuse has been blown. I did'nt fix the problem myself, but the local service outlet did; so I cannot help you with the exact sparenumber of the fuse. You may find this SMD-part in the Control Unit.

Don't hesitate to drop me an e-mail if you have any further questions about this problem.

Good luck and happy 2003 to you too!

FWIW there is now only one AM stereo system in use. (the Motorola
system)

Not that I can tell you how it works. Someone was offering decoder
chips for sale a few weeks back, I can't remember where.

Roy Lewallen wrote:

>A search of the manufacturer's web site for "SPICE" should get you to
>the right spot.

On-site search engines are sometimes pretty dumb, and may not find
things that you know darn well are there.

If you have problems, try using a much smarter search engine like
www.google.com/advanced_search

In "With all of the words", enter SPICE (Google ignores capitalization).
In "Domain", enter the site you want to search, eg manufacturer.com
Now click "Google Search", and if it's anywhere on that site, Google
will probably find it.

Unfortunately, not all sites will have SPICE data. If the manufacturer
provides SPICE files, you'd naturally expect the data to be accurate...
but that takes effort, time, and money. For complex devices at high
frequencies, it can become so difficult that even the device
manufacturers don't know exactly how to do it - they subcontract the job
to specialist companies. Having spent all that money, they may not feel
like giving the information away for free.

So, as others have said, if it's a very simple device you'll probably
have to edit a default SPICE file yourself. Also look for similar
alternative devices, and see if you can find files for them instead.

Don't worry if you have to make a few blind guesses, because eventually
you ought to check the effects of changing any of the major device
parameters. If your circuit is very sensitive to component values and
device parameters, then maybe you need to improve the design and make it
more tolerant.

The more tolerant your design is, the less you need to worry about
accurate modelling, and the better it's likely to work in real life.

Did you put this offer up on the boat anchors newsgroup? :-) Actually,
it's not a bad idea to do so.

Steve

While it is not an iambic pattle system, you could use an old computer mouse. Remove the ball, strip the cord and use a continuity tester to see which wire goes to which microswitch. Then apply those wires to the keyer and use the remaining wire to form the keying system line.

There is plenty of DOS left in Windows, just make a boot disk!

You could build a filtering circuit with inductance coils to pull out stations in your proposed way but they would have to be operating companded sidenband, which is highly unlikey. Companded sideband is almost never used in the broadcast world because of the filtering requirements. BTW Companded sideband is when a station trasnmits both sidebands but no carrier. The carrier must be placed back in, in the reciveing stage with a filter.

There is plenty of DOS left in Windows, just make a boot disk!

That's one way to do it. If Q1 and Q2 are matched (to 1% ?), this can be so.

A better way is to measure the actual collector current of Q1 and Q2, and adjust their individual base drive (idle) currents for equality. However, the AC gains of Q1 and Q2 are not exact, nor are T1 and T2 perfectly balanced, so measuring idle DC (standby) current is only a rough approximation.

Larry,

Although replying through email would be easier, I think it's better to continue the analysis here, so that other people can learn something as well.

Actually the biggest problem I have with the circuit, is that I don't know anything about the final transistors. They are both PT9790, made by Motorola about 20 years ago, but I never found any datasheets on these 'exotic' transistors. I found out that R2 is getting rather hot, even when not transmitting, so I assume the bias is way too high. I'd like to find a good way to bias the transistors. To do this I have to understand the bias circuit 100%. I have some kind of a manual from this thing, but it only says : set the quiescent current to 300 mA. Is this 300mA the current going through each transistor ? Or is this 300mA the total current through Q1 and Q2 ? Or maybe the total current of the entire module. I haven't got any clue. This is what keeps my busy these days :-)

Maybe the PT9790 does ring a bell on your end ?

Mario.

Mario -

Yes. The PT9790 transistor was used in Transworld RF amplifiers,
that I saw in a number of surplus units 6 to 7 years ago.
http://www.lxoindustries.com/rftransistors/

A German firm at one time had the specification sheets, but when I talked to
RF Parts,
as that time, Merit (W6NQ - I believe), advised me to use the MRF429 spec
sheet.
http://www.s-direktnet.de/homepages/sangmeister/daten/attent.htm

The MRF429 is usually the equivalent substitute. [Uses a .500 flange]
You MUST replace these transistors in pairs.
RF Parts does sell matched pairs (MP)
http://www.rfparts.com/mototran.html

The temperature rise of the terminating resistor of the associated port in the output coupler will
usually tell you how well the current pair of transistors are matched.

Hope that helps.

Greg,

Thanks for the reply.
The MRF429 is a good substitute. So the quiescent current should be more
or less similar ?

Hello,
Does anybody have the electronic diagram of the Oak Hills qrp (20mtrs), CW.
It is the older version of the qrp, not the latest. I bought the qrp without
the diagram, RIT is out of order and tx/rx frequency is off set. Please mail
me the diagram.
Thanks in advance.
Adam, 9a4qv

Hmm. Someone told me about an old reciever that could use just a single sideband. It didn't matter if the station sent the carrier or not, it didn't use it in the special mode. I'll see if I can find anything more about it. Thanks,

David

Can't figure out what kind of diode this is??

Looks like a 1N914 but (glass and about the same size) BUT it has a BLACK
and WHITE line on it? LIKE THIS BELOW!

I'd hazard a guess and say that the stripes are the cathode end of the diode. Why not check it with a meter ?

Steve

I've seen PLL and DDS used to create signals for IF's and tuning. What are the pros and cons of the two systems? Are there single chips available for them suitable for use in recievers? I'm trying to design a versatile digital tuning module that I can use in my homebrew recievers and stuff.
Thanks,

David

A first stop might be
http://www.analog.com/UploadedFiles/Application_Notes/70863939AN557.pdf

It's an applications note for a ham VFO based on DDS. Includes circuits and
PCB layout plus very useful information regarding DDS. Analogue will provide
2 samples of the IC for free.

Also check http://www.analog.com/UploadedFiles/Application_Notes
for other app notes on DDS and PLLs

If you can not find a suitable BCD counter from any common logic
family, you can always connect five master-slave flip-flops into a 5
stage Johnson counter, which should do the trick, provided that the
flip-flops works at 144 MHz.

4811. Re: Diplexer improvements (was Re: First mixer in Drake R7/TR7?)

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-12-30 18:29:09 UTC
From: Kevin <rfman@xtra.co.nz>
Message-ID: <3E109075.F38C8499@xtra.co.nz>
Source record: 38973

Hi,
I did some work on simple mixer terminations on a High IF Milspec HF radio some years ago by adding simple series C and R terminations to ground on all ports (R= 50 ohms & Xc= ~200 ohms at used frequency eg IF,RF,LO).
These would terminate the higher frequency harmonic and mixing products. Just
one these terminations on one of the ports (cant remember which)improved the
Intermod performance(IP3) by 10 dB over part of the HF band. However adding all of them broadbanded it across the whole of the HF band.

The simple termination would probably loose a db or so but would be offset by improved mixer performance due to mixer termination. The mixer had filters on all ports.
Mixer terminations need to be done right at the ports as the performance degradation as one moves away through other components can be significant.
(IF components like 10 nF capacitors in series may effect the termination.
Learnt that on my 432 MHz transverter)

DC offset (due to diode balance or mixing products) can also be a factor and if the IF port is used as the IF port some designs have a choke to ground additionally.

4813. need help understanding regen for class project

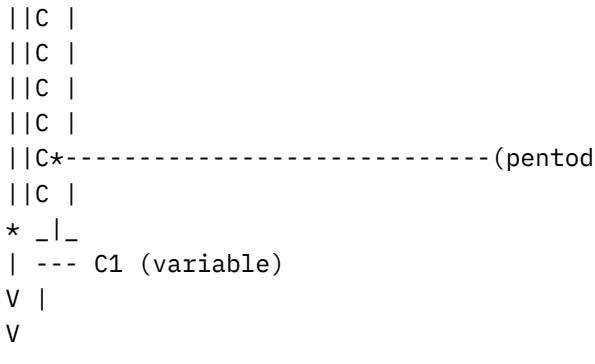
Newsgroup: rec.radio.amateur.homebrew
Date: 2002-12-30 19:21:31 UTC
From: Ross <rjtucke@asu.edu>
Message-ID: <rjtucke-858274.12235230122002@news.west.cox.net>
Source record: 38975

This is my first post on rec.radio.amateur.homebrew and my second usenet post in my life. I've been licensed for a few years and in my undergraduate Physics curriculum this past semester, I successfully built "A 40-Meter Regenerative Receiver You Can Build" (By David Newkirk, then WJ1Z, published in _QRP Power_ and /QST/, September 1992, page 35). (This was an extra credit project, obviously.) The circuit uses two 6GH8A triode/pentode tubes in a circuit decended from George Grammer ("Rationalizing the Autodyne," QST Jan 1933 page 11-16, 23). With the names I've seen on this group and the high level of electronics radio magic you all work, I know I am asking a lot to brazenly barge in with my youthful ignorance, but I assure you that my respect and honor are commensurate with my obvious impertinance.

Now I have been able to analyze the AF stages (triodes) in a complete mathematical description (with very few simplifications) and have developed an Excel simulation that works (I _think_!) But I am really completely STUCK on the detector for two big reasons.
One is that I've only ever been able to find big ugly models for the pentode (for use in SPICE simulation). And I'm not exactly sure how to even fit these to my tubes (6GH8A's), though I do have plenty of data sheets.
Two is that I don't get the detector circuit.

I know I don't have a big probability of getting any replies because I don't have a scanner to show you the schematic- the intersections of the sets of people who can and would help me and the set of people who have QRP Power/QST1992 is probably not too huge. So let me make an attempt to ASCII-art the thing a bit ("and in the process irritating EVERYBODY who would help away with my verbosity" says my cynical side)
Values:
Inductor ("L1") is "about 1.7 mmH", 19 turns on T68-6 tapped at 1 turn above ground (to the pentode's cathode). (there is also a fine-tuning cap at another tap-- omitted for simplicity)
Tuning cap ("C1") ranges from 180-280 pF.
Grid leak resistor ("R1") is 1M.
Grid leak capacitor ("C2") is 100 pF, NP0.
There's also a 1 pF, NP0 feeding from the prev stage.

```
C2
----| |-----
Input | |
| | |
|-----*--------*--/\/\/\--*---(pentode grid)
* | R1
L1 ||C |
```



Of course, the V symbolizes ground, and * is connection

The regeneration circuit feeds into the screen grid- I don't see a feedback path, though. I think it simply adjusts the DC voltage! If anybody requests it, I will ASCII-ify it (very simple), but as mentioned, I suspect I'm WAAAY long winded anyway.

The output comes off the plate with an LC low pass filter to dump RF to ground and let AF through. I'm fine with this part.

The input (before the 1pF NP0 cap) is from the RF stage plate (of course), but there is one interesting thing. The plate supply has (looking from B+ rail) a bias resistor, a massive bypass cap, alarger bias resistor, a smaller bypass cap, and an RFC. I mention this because at 7 MHz, the reactance of the RFC is equal to that of the 1pF NP0 cap to the next stage (detector tuned circuit). The bypass cap on the B+ side of the RFC has low reactance, and so I see that the incoming signal sees equal reactances to ground (through RFC in plate supply) and the detector (through cap). And the tank circuit is after my cap, so isn't this essentially dumping half the useful output of the RF amp to ground through that RFC?!?

Now finally, I gather that this is a grid-leak detector with a Hartley oscillator, but HOW DO I ANALYZE IT?

Again, I'm VERY sorry about the length of all this. Many many many thanks for putting up with me and (hopefully) offering any ideas. I really appreciate your consideration.

Most sincerely,
Ross

Source record: 38977

Doh! Correction on my part- the reactance of the RFC on the RF amp B+ supply line is NOT equal to the 1pF cap. It is a 500 uH RFC, giving a reactance at 7 MHz of +3500j ohms, versus about -143,000j ohms for that feedthrough cap. So that removes a coincidence, but a mystery still remains- that means the impedance for the signal path is more than FORTY TIMES greater than the impedance of this ground path... what gives?
Ross

AFAIK, this isn't a very effective way to improve IMD. The reverse
bias method works better. This was all explained ~20 years ago in
a paper by a W-J engineer in Microwaves & RF.

Hello all who responded to my question concerning the humming...

It seems as though I have finally licked it.

I started out using my regular RG-58 coax to the open half wave
dipole antenna.

Conclusion: Humming is there.

I then put a 5600uF electrolytic capacitor in parallel on the output of
the power supply.

Conclusion: Humming is still there, but just a 'little' less.

I then changed out the coax to an RG-6 (that large 50 ohm coax) together
with the 5600uF in parallel.

Conclusion: THE HUMMING IS TOTALLY GONE!

I want to thank everyone for added inputs to my challenge. I wanted to
state how I got rid of it. I did many things, but when I did, what
was mentionied above, it finally went away...all the way!

Again, thank you for the kind input and a very happy New Year to all!

Sincerely,

Patrick Cambre

P.S. I want to add this...to all the ones that replied back to me.

I have made an amazing one transistor FM receiver. Total component count
in the receiver itself is 12. Then I added the typical LM386 to boost
up the volume.

I know many look for these simple things on the www, so have I. But I
could never find one to my likings.

I could tell you the whole story how it came to be, but my website will
do all that.

I call it the Radio Shack Special, since all of the parts may be
purchased there.

Without comprimising senstivitiy, selectivity and audio out, this little
jem is doing it's job just fine. I am still amazed how it works so well,
with so little.

When you get to the website, scroll down until you see the words...

The Radio Shack Special Project

...and under that will be all the people who have made it and responded back to me, telling me it is truly a littl marvel. Yes, read what Pedro, Phillip and Murphy had to say about it.

I do believe just going all the way and building it...is really a gamble. But when you read what these people had to say about their own story, you will have more of an incentive to know that IT CAN WORK EXTREMELY WELL!

My main website, which is a free account with Freeservers, does go over the bandwidth every now and then...toward the middle of each month. As I speak, the site is disabled. But come Jan 1st the site will be open again. Please wait until that time and you will find the project there...waiting for you.

My website is at: http://braincambre500.freeservers.com

In case the website again goes disabled during the month of Jan, I have a special backup site I can also give you...while you are waiting for the main site to come back on the 1st of Feb.

With all that said my friends, I tip my hat to all those who have helped me through my 'humming' challenge!

Ross ---

I would suggest that you also post your questions to the following newsgroups: rec.audio.tubes, sci.electronics.components, sci.electronics.design

Between this newsgroup (rec.radio.amateur.homebrew) and those other 3 groups, I'm very sure some sharp folks will be pleased to help you out.

Good luck !!

==========

>a paper by a W-J engineer in Microwaves & RF.
>
>Rick N6RK

This is very interesting to see, but would work for 1N4148, too. The
RC pad might equalize the differences between diodes? On the other
hand I'll keep using the different mixers when they are supposed to be
good enough, but don't find 1N4148 type mixer to be a good choice when
a ready off-the-shelf type is available and solves the problem

Just noticed the MacKay 3010-B*) receiver used 4x 1N82 diodes as first
mixer (up-converter) in an otherwise tube-type construction. Suppose
this is a very early application of ringdiode mixer for communication
receivers, although they have been widely used for telephone line
equipment many years earlier. See http://bama.sbc.edu/ .
Believe 1N82 is a germanium diode. *) The manual is dated July 1964.

David, I would have to say that DDS is probably the better method these days, although there is a good chance that a combination of DDS and PLL will be the thing you need to do.

DDS will give VERY high resolution steps, less than 1 Hz between steps is very easy, and it is extremely stable and repeatable.

However, DDS by itself tends to have discrete spurs on it's output due to various reasons, and most of the reasonably low cost chips have upper frequency limits too.

PLL doesn't have the same types of spurs, but it steps in something like several KHz for each step. That has to do with loop filters, phase noise, and a lot of other engineering compromises.

So a lot of people use DDS combined with PLL to get the high frequencies for the LO but keep the 1 Hz steps a DDS can achieve. The PLL can also serve to clean up a lot of the discrete spurs DDS chips tend to have.

I see some of the other replies show websites and application notes that will explain in much more detail and so on, but I hope this gives a general understanding of some of the differences in the two approaches.

==========

Analog Devices have wonderful DDS chips, they seem to be the leader in the technology. I would indeed check their website and their App Notes.

As for PLL chips, there a quite a lot of manufacturers with single chip solutions, National Semiconductor among others.

Keep in mind that both PLL and DDS will require programming for each frequency, and it tends to be a serial bit stream so in addition to the synthesizer, you will need some sort of microprocessor and probably an LCD display screen to show the frequency.

You're looking in the wrong place.

> I think it simply adjusts the DC voltage!

Adjusting the screen voltage of that circuit adjusts the gain of the stage. No voltage = no gain, low voltage = low gain, etc. Feedback is not adjusted in that circuit - gain is.

>this essentially dumping half the useful output of the RF amp to ground
>through that RFC?!?

Oh yes, but that's not a problem. The RF stage is not there for maximum gain. Its main purpose is to isolate the detector from the antenna. Gain is secondary.

The Ancient Ones were working the Antipodes on 40 meters with QRP and wire antennas more than 70 years ago using rxs much simpler than that one.
>
>Now finally, I gather that this is a grid-leak detector with a Hartley
>oscillator, but HOW DO I ANALYZE IT?

First you have to understand it. The feedback path is via the cathode tap on the tuning coil. Feedback is set by how far up the coil the tap is.

I don't have models for the pentode, but here's a basic description: In this circuit, it's a voltage controlled dependent source. Signal input impedance is essentially a vacuum diode in parallel with a few pF capacitance to ground and cathode. Output impedance is very high (megohm?). In addition to the source being controlled by the input (grid) voltage, it's also controllable by the screen voltage.

I was planning on using a PIC chip with 5 7-segment LED display for the
frequency. This section would then have shielding around it to reduce
interference. Thanks,

David

Uhhhh... Excuse me? RG-6 is also known as 'Aluminax,' and has a
characteristic impedance of 75 ohms. It finds use in cable TV hookups,
for the most part.

Of course, if you're using it as DC power cable, that may not be
relevant. ;-)

Keep the peace(es).

Source record: 38990

Functioning of a super-regerative receiver is quite simple. There are two modes, A and B.

(A) Oscillation builds up exponentially from an ampltude begining at the initial received signal level. Oscillation builds up to a constant maximum value at which it blocks itself off. It squeggs.

The greater the incoming signal level the shorter the time taken to build up to maximum amplitude and the heigher the squegging frequency. The oscillating device's DC component then increases with squegging frequency and hence incoming signal level.

(B) The squegging frequency is that of a separate fixed-frequency oscillator which modulates the DC supply of receiving oscillator. The receiving circuit is a modulated oscillator.

Again, oscillations build up exponentially from a level depending on the incoming signel level. But now oscillation amplitude does not build up to a constant value - it builds up only to a value allowed in the time of one cycle of the separate fixed-frequency modulating oscillator.

The DC component then depends on the amplitude to which oscillations build up and so, once again, on the incoming signal.

==========

The superegen clearly responds best to amplitude-modulated signals. For receiving audio modulation the squegging frequency is usually in the range 50 to 100 kiloherts. Least distortion occurs when a separate squegging oscillator is used. The circuit is more linear.

With delicate adjustments it can be made to demodulate FM signals. But due to instability it is not recommended.

The self-squegging/blocking frequency (50-100 kHz) of a receiver is adjusted by the capacitor/resistor time constant of the grid/base/gate circuit. It is very non-critical.

Superregen receivers are characterised by EXTREMELY high sensistivity but VERY wide receiving bandwidth. This means they are prone to interference from adjacent channels. The high noise level at the output of the demodulator stage is no disadvantage - it is just an indication of of the high sesitivity even to thermal noise in the antenna.

Historical note: A WW2 application was used by the RAF in IFF (Identify Friend or Foe) airborne equipment on 176 MHz. The receiver picked up friendly ground radar signals and because the reciever was a sqegging oscillator at the radar frequency it re-transmitted the radar pulses back to

where they came. So the radar echos were returned greatly magnified and could be detected by friendly ground stations at great range. But the clever part was on/off binary coding of the returned echos. By knowing the code ground stations could identify particular squadrons, even aircraft.

The IFF receiver was simplicity itself - a single 1-watt VHF valve, top grid and anode, which, of course, was also the transmitter.

It was essential not to allow IFF equipment to fall into enemy hands. It was contained in a box about 1-foot cube and contained an explosive charge designed to explode with sudden acceleration as when crash-landing in enemy territory. Unfortunately when returnig to base it was easy for the crew to forget to switch off the electrically-operated detonator and when the aircraft decelerated on landing there was often a loud bang from the rear where the IFF gear was located. The equipment cube almost changed to a sphere.

There were navigation equipments using similar principle, the coded superegen receiver/transmitter being ground based and the interrogator being in the aircraft. The ground-based equipment was, of course, a coded VHF beacon for returning home.

The problem with the explanation is that the poster is asking about a
regenerative detector, not superregen.

And I think a lot of the mystification of the superregen comes from
treating it as a standalone design, rather than a regen detector
that has been modulated by an ultrasonic signal. That whole self-quenching
bit, while obviously making the thing easy to build, doesn't make
it's operation as clear as when an external oscillator is shown.

Armstrong himself showed an external quenching oscillator in his
patent application.

But are you trying to understand this specific circuit, or just
regenerative detectors in general?

A regen is just an oscillator with some sort of control to reduce
the oscillation. Or to look at it another way, an amplifier with
positive feedback and a means of controlling it.

You can read Armstrong's patent for the regenerative detector
at the US Patent office website, http://www.uspto.gov/patft
The patent number is 1,113,149. While you're there, you
can also look at his patent for superregeneration, #1,424,065
which was issued 8 years after the regen patent, and two
years after his superhet patent, $1,342,885.

Once you understand how a regen detector works, then you
can see that there are plenty of different circuits, oscillators,
that can result in the same scheme. It looks like the oscillator
in the article is a Hartley. Reading up on it might help
you to understand how the circuit is supposed to work. Armstrong himself
has an oscillator named after him, the Armstrong oscillator, and I'm pretty
certain that was the circuit he described in his patent for the regen
detector. (I don't think I've looked up the regen patent, though
I have looked at the superregen patent diagram.)

I'll try look over the article later, and reread your post.

hi Ross:

i am new here also (first post). while i have limited understanding of regen using tubes, i will give this a go in general terms [looking at your ascii art] and let the experts correct. although people draw things differently the level of "pentode cathode" is what i would call "ground" under Hartley.

R1 under gate-leak (probably same for grid-leak) could have been connected to "ground" as this is an alternate method for the circuit. the cap and resistor are used for gate leak bias. bias places the proper DC potential [or flow] onto an active device [often setting class of operation].

L1/C1 puts an AC voltage on the grid. when the grid is positive it draws current from the cathode and C2 will be charged negative on the L1/C1 side and positive on the tube side. after oscillation, voltage steadies and provides bias.

the control grid and the cathode form a diode rectifier. usually there are three flows to think about: tank, bias, and feedback. tube output [via cap] will be connected back at the inductor tap. in Hartley's design Armstrong's "tickler" is just part of the resonant tank's inductor. the tap position on L1 [fixed] and variable cap inline [control, not shown in your ascii art] set the amount of positive feedback (aka "regen").

> The regeneration circuit feeds into the screen grid- I don't see a
> feedback path, though.

regeneration is happening at the inductor. the small tapped (lower) part of L1 [think "integrated tickler"] is part of an auto-transformer: this provides feedback. tube output should be connected to a capacitor (going to this "tickler") and an RFC (RF choke keeping signal out of the supply).

hopefully this is accurate and not over simplified... sorry, no tube wizard here... i like FETs! FWIW while 1M and 100 pF are considered the "standard" grid/gate-leak values they are often not ideal: unload.

regards,
phil

Yes, that is a good 1st approximation. I hv a description in my Motorola book, of the identical ckt used in your amp. I can scan the two pages as a JPG or PDF and email to you.

Let me know.

LarryC

hi David:

while AM stereo is not popular, these chips are great for synchronous AM (important in reducing selective fading). one way to select a sideband on AM (other than phasing) is by using narrow filters under sync while applying the PBT or by changing the main LO (aka changing the tuned frequency) by plus or minus half the filter's width. example: for 640 AM engage a 2.4 kHz filter (-6 dB spec) and tune 641.2 (upper side) or 638.8 kHz (lower side).

ideally go with double conversion: first high IF for image rejection, second low IF for selectivity (455 kHz filters). tuning AM stations as if they were SSB (some call this "ECSS") is extremely effective at adjacent channel rejection. for more chip information look up the following data sheets:

Motorola C-QUAM AM Stereo MC13022 or MC13122
Phillips TDA1072 or the TDA1572

check out http://users.hfx.eastlink.ca/~amstereo/ [chips $5] and the AM Stereo Yahoo Group. FWIW IMO the most important ingredient for BCB DXing is getting a directional antenna. outdoors build a beverage or K9AY loop or phaser [very cool, do a search for Mark Connelly or join NRC or IRCA]. indoors build a box loop or amplified ferrite loop. BCB is great... have fun!

You might consider an LCD rather than an LED. The LED requires a lot of support hardware and will challenge the number of I/O pins available on the PIC unless you add a bunch of shift registers and latches. The LCD needs about 7 of your PIC's I/O, 5 volts, and that's it.

Also, take a look at some of the TI parts. The TRF4400, TRF4900, TRF2050, and TRF2052 include both the DDS and the PLL, and are a whale of a lot cheaper than the AD parts, plus they are available. AD parts are tough to get other than as samples (and I view that as a little dishonest in that I don't intend to buy a thousand of them). The TI parts are all pretty high frequency, so after you've divided them down to something reasonable all their hard work in making a sine wave is wasted, but it sounds like you'll be going into a mixer anyway...

..

Hello Sir Bruce,

Yes, I apologize for that incorrect cable. It is, I do believe, an RG-8. Yes, my father used to use that for his 'Browning Eagle' back in the 70's when CB was a big thing.

That old reciever uses exactly the same technology I am speaking of.

There is plenty of DOS left in Windows, just make a boot disk!

I have seen gunnplexer diodes similar to that. It could possible be for some microwave application.

It's in the HF/VHF sensor of the Diamond SX-1000 watt meter. The meter was hit by lightning and I'm rebuilding it. I use a 1N914 and it's not working right (the meter that is) so I'm guessing that there is something special about it?

Wow, thank you all VERY much for your suggestions- you are very kind and
I feel honored by your attention. I'm now attempting to implement these
ideas- we'll see how it turns out! Once again, I thank you.
Sincerely,
Ross
